ACKNOWLEDGMENTS

The authors wish to acknowledge the considerable support given by the Project Task Force. Dr. Freddy Nachtergaele is thanked for his overall contribution to the present work.

The work of Somali soil surveyors Omar Haji Duale and Ali Ismail Ibrahim, as well as the logistic contribution of Mohamed Jama Gahay, are highly appreciated.

Thanks should be addressed to Dr. Otto Spaargaren from ISRIC for his valuable assistance in revising the soil classification of the main soil profiles under the WRB 2006 system.

Many thanks go to Mr. Jan Venema for the technical revision of this study report.

Finally we want to express our acknowledgment to all technical and administrative SWALIM staff, especially to Antony O. Ndubi, as well as to the management for their continuous support and contribution.

1 INTRODUCTION

Soil information is a key element for natural resources management, and specifically land use planning. In developing countries like Somalia where there is no national spatial data infrastructure, soil data and information is very scarce. Conventional soil surveys were and are the most frequently used method of acquiring soil data at different scales, for various purposes. This is a highly cost- and time-consuming activity, which limits its use over broad scales.

As mentioned by McKenzie *et al* [1], technological advances during the last few decades have created tremendous potential for improving the manner in which soil maps are produced. Remote sensing and photogrammetric techniques provide spatially explicit digital data representations of the Earth's surface. However, in the case of soils, it is less effective due to limitations such as showing information only of the soil cover, and not the depths where soil development takes place. Although these tools can improve soil inventory techniques, soil surveys are the only way of acquiring and understanding the types and properties of soil/s present in a specific area.

Soil surveys in Somalia were primarily undertaken between 1961-1988. There have been no national soil surveying and mapping initiatives at the institutional level. The most important regional soil reconnaissance surveys were conducted in the Jubba and Shabeelle region by FAO-Lockwood in 1967, and another in the northwest area of the country conducted by Sogreah in 1981. Some reconnaissance studies are shown in Table 1.

Table 1: Soil studies

SURVEYOR	LOCATION	AREA (km^2)	SCALE
ICA (1961)	Lower Jubba Valley	4.500	1:650.000
Selchozpromexport (1965)	Lower and Middle Jubba Valley	16.000	1:200.000
FAO/Lockwood (1967)	Project Area	208.500	1:60.000
Technital	Jubba Valley	50.000	1:200.000
HTS (1977)	Project Area	200.000	1:500.000
SOGREAH (1983) [2]*	North-west Somalia	33.500	1:100.000
Sir William Halcrow & Partners[3]	Northern Somalia		1:200.000

***The only soil survey covering SWALIM's study area.

The SOGREAH study was part of the north–west region agricultural development programme. This programme was initiated due to the fact that, after the two major river valleys of the south, the North-West region is the next most populated part of the country with Hargeisa having the highest population. Natural resources inventory and evaluation was carried out between 1979-1983, including a soil survey as one of the main activities, which was later used for various agricultural development initiatives.

Since the start of the war in 1991, no soil surveys have been undertaken and available soil data produced by SOGREAH has been lost, including maps showing spatial variability of soils.

In view of the foregoing, and considering future planning activities in the country, there is a need to generate baseline data that provides an accurate reflection of the current status of natural resources.

SWALIM is mandated to produce natural resource baselines for specific areas of interest, including the north-west. To this end, a soil survey was conducted using a combination of modern and conventional approaches (to overcome the various constraints within the

study area) to map spatial variability of soils as a primary input to land suitability and land degradation assessment components of SWALIM's activities.

The objective of this study was a soil survey which would include soil mapping activities at a multi-scale level, oriented towards a variety of users.

2 STUDY AREA

2.1 Location and delineation

The study area of the Northwest Somalia is located between the latitudes 9^{o} 10' 30.8" and 10^{o} 41' 36.54" North and the longitudes 43° 0' 52.3" and 44° 27' 54.22" East (Figure 1) thus covering a total area of 12 915 km^{2}. It is bounded in the north by the Gulf of Aden and Lughaya District, in the east by Berbera District and the eastern parts of Hargeisa District, in the south by the Ethiopian border, and in the west by the Eastern part of Borama District.

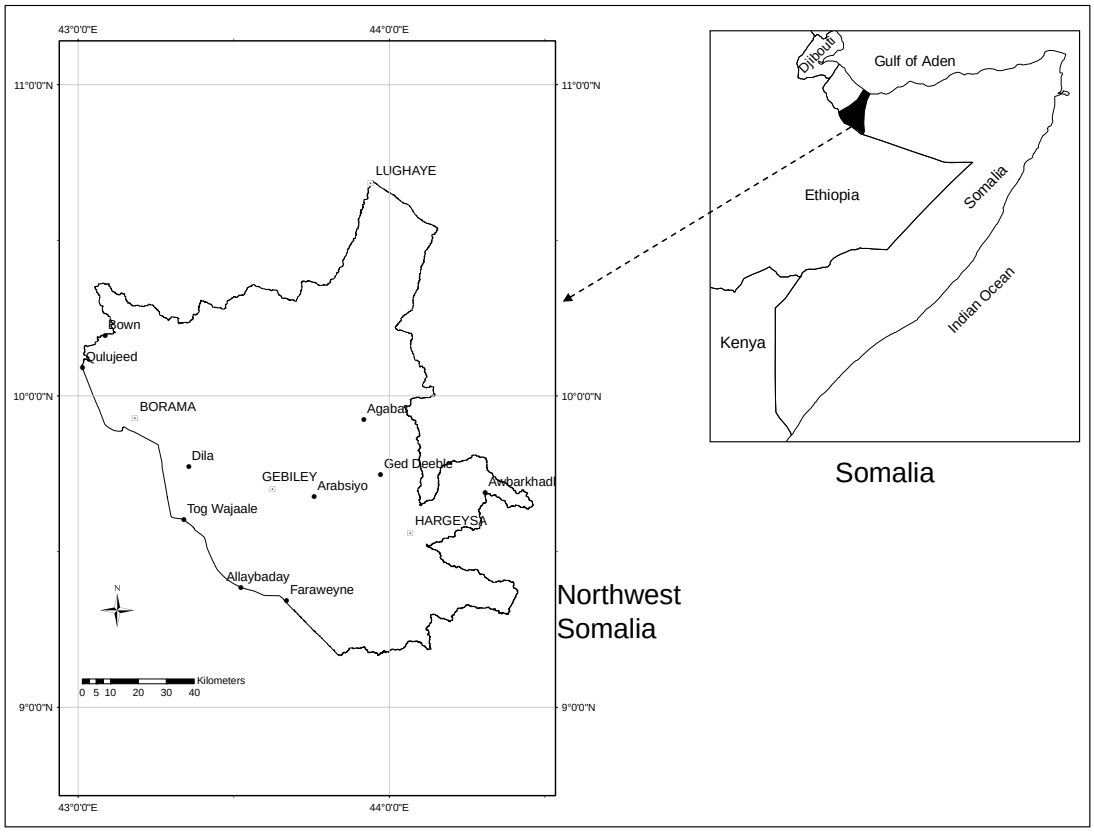

Figure 1: Study area

2.2 Climate

The region lies at the extremity of the sub-Saharan semi-arid zone commonly referred to as the Sahel, which traverses the continent from Senegal to Somalia.

The climate of the study area is hot dry desert in the coastal plain (Lughaya and northern part of Baki districts) and arid in Borama and surrounding area. Semi-arid conditions prevail at the higher altitudes of the Al Mountains and south of Gebilley. Mean annual rainfall ranges from below 200 mm in the coastal area of Lughaye, to 500 - 600mm in the east of Borama and surroundings, while the rest of the study area has a mean annual rainfall of 300 - 500mm (see Figure 4).

The study area lies entirely between the two subtropical anticyclone belts. The main weather pattern is controlled by the passage of the seasonal monsoon winds. Rainfall in the area is thus bimodal (see Figure 2). The northeast monsoon brings the primary *Gu* rains from March to June, followed by a hot dry period called *Xagaa* in June and July. Short rains locally known as *Deyr* also occur between August and October followed by cool long dry *Jilaal* period between November-February.

Temperatures in the area are influenced by altitude and the strength and temperatures of the seasonal winds. Figure 3 shows how temperatures decrease with increasing altitude. In the higher altitudes of the Al Mountains and Plateau areas temperatures vary considerably with the seasons, with a mean annual temperature of 20-24°C, while the coastal region has mean annual temperatures of 28-32°C.

Relative humidity of the highlands is mostly around 40%, except during rainy periods when it may go up to 80%. High temperatures in the coastal areas combine with a high relative humidity of more than 70% to create an exceedingly hot, humid environment.

The major winds in the study area occur between June to July during the *Xagaa* dry season, during the southwest monsoon and in *Jilaal* between December and February. Hot, calm weather occurs between the monsoons during April and September). Generally, in the north-west winds are strongest during the southwest monsoon. Average wind speed varies between 8 - 10 m/s, but during a large part of the year strong winds of up to 17 m/s occur, causing frequent “dust-devils” over the coastal plains and plateaus.

The study area is subject to high potential evapotranspiration (PET), with an annual average of between 2000 and 3000mm. Annual rainfall is far less than the PET and a significant water deficit exists throughout the region for most of the year. Rainfall is not always sufficient for successful crop production (Figure 2).

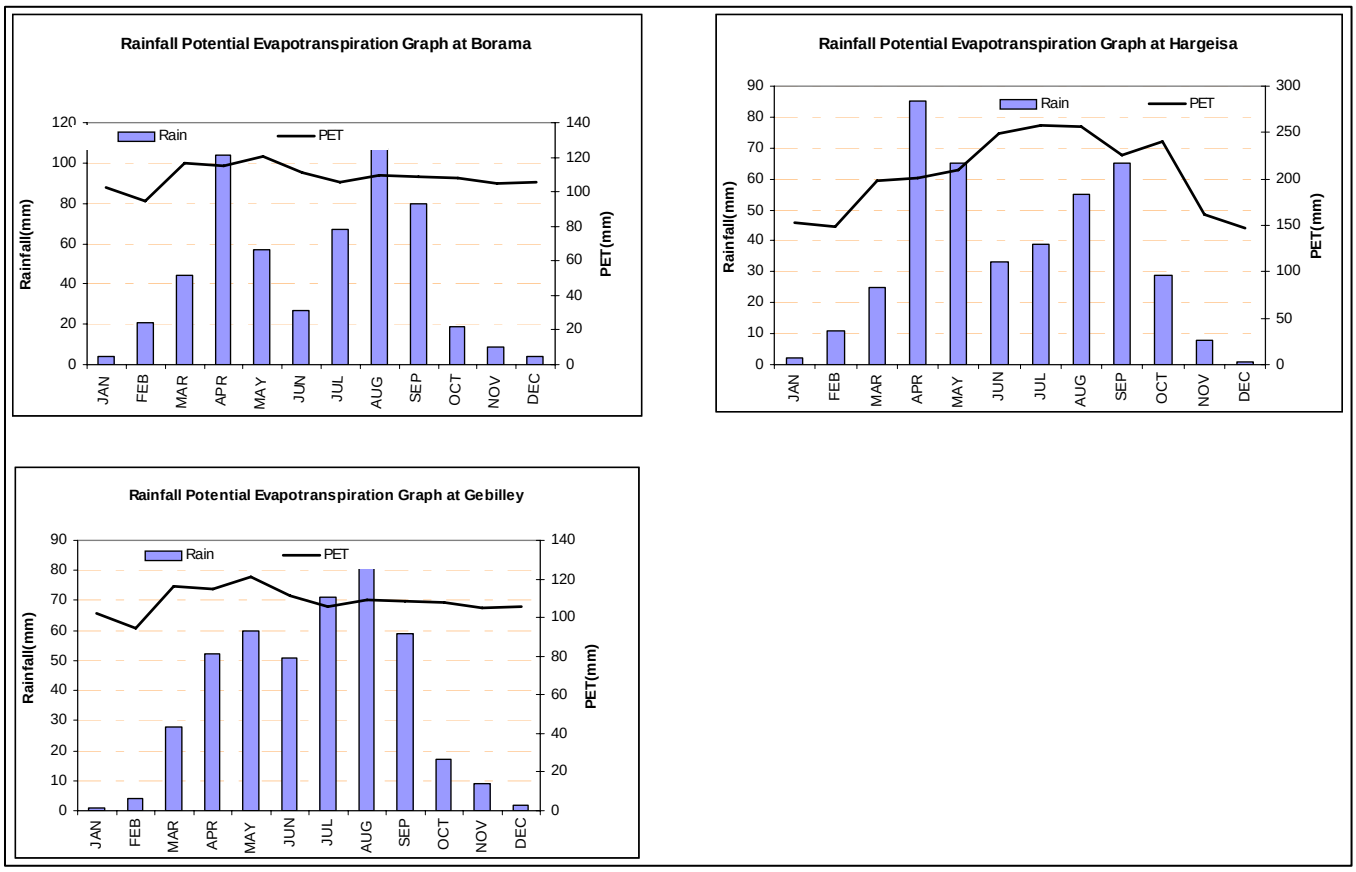

Figure 2: Rainfall and potential evapotranspiration

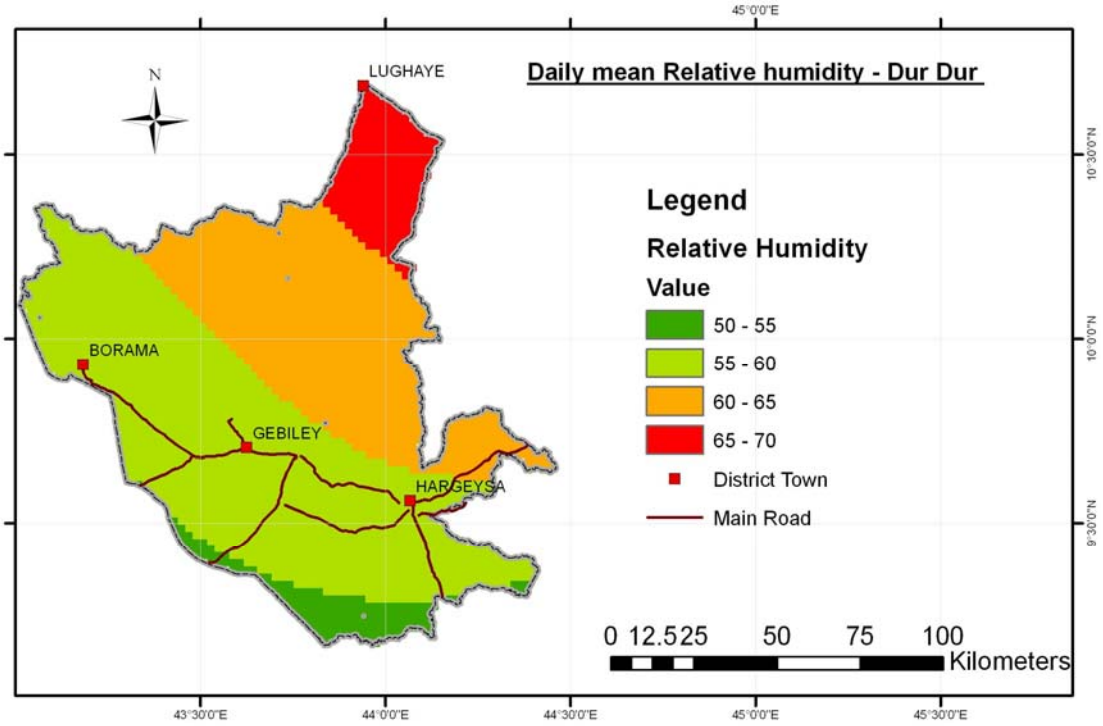

Figure 3: Relative humidity of the study area

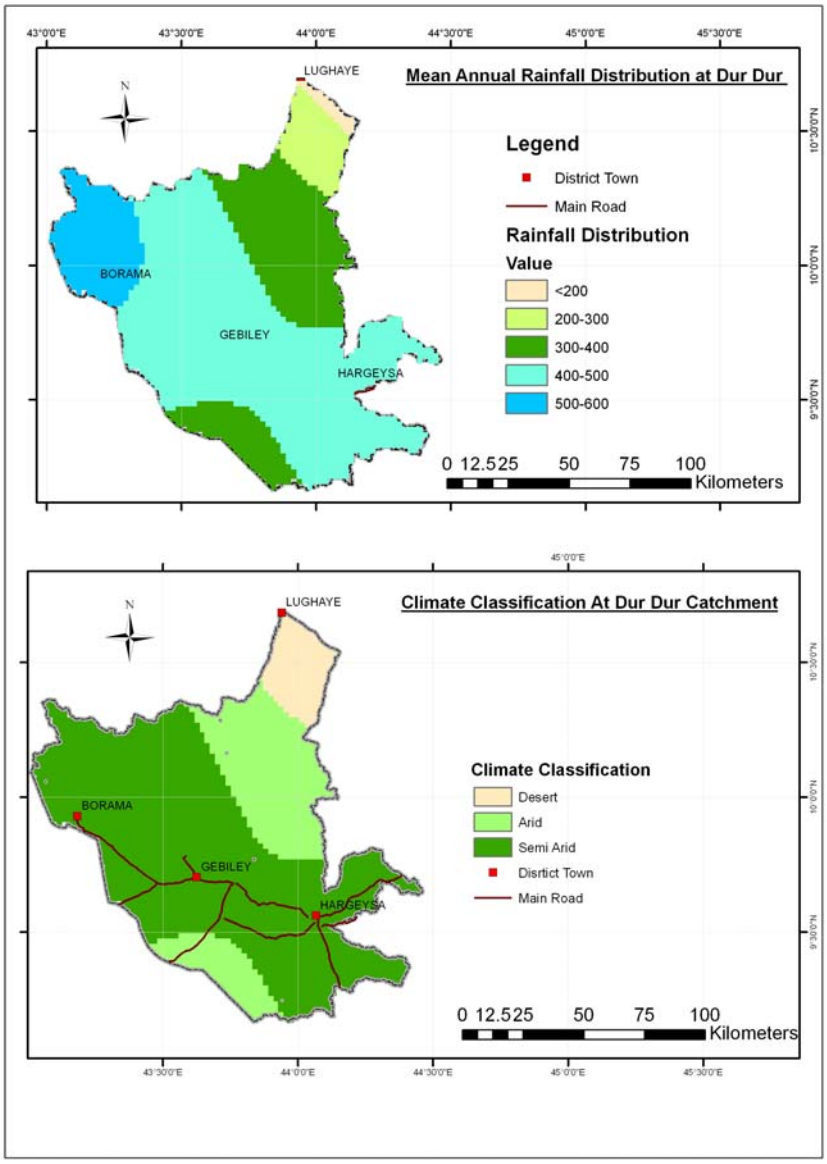

Figure 4: Rainfall distribution and climate classification of the study area

2.3 Geology / Lithology

The study area is covered by rocks dating from Pre-Cambrian to Recent, comprising sedimentary, igneous and metamorphic rocks. The tectonic arrangement of rock outcroppings in the region is complex and severely affected by many different systems of faults and fractures, mainly oriented parallel to the coast (i.e. WNW-ESE).

The basement complex covers an extensive area in Al Mountain around Borama and Baki districts. In other parts of the region, it is covered by Jurassic limestone and Miocene bio-limestone, Pleistocene basalts and Recent alluvial and aeolian deposits. The igneous rocks consist mostly of basalts and rhyolites, and metamorphic rocks include a wide range of schists, ortogneiss, quartzite, migmatites, marble, calcosilicate and paragneiss, intruded by granite, diorite and gabbro.

Pleistocene basalt outcrops and other volcanic rock outcrops occur dispersed along the northern escarpment and coastal plain.

2.4 Landform and Soils

From a geomorphological point of view, the study area may be divided into three landscapes: (1) Piedmonts and the Coastal Plain, (2) Mountainous and Hilland, and (3) Plateau (both dissected and normal). The middle mountain range and the southern plateau are locally known as *Oogo*. There are three main ephemeral river systems that drain from the plateau and traverse the mountain range in the direction of the Red Sea, and from the southern side of the same mountain to the southern highlands respectively. They are called *Togga Durdur*, *Togga Biji* and *Togga Waheen*.

(1) *Piedmonts and the Coastal Plain*. A small northern section of the study area is taken up by gently sloping coastal plain (locally called *Guban*) with elevation ranging from sea level to 600m, from the Red Sea southwards up to the foot of the mountains (see Map 1). It is characterised by debris and colluvia carried by several togas crossing the plain to the sea. The beds of the togas are very wide, and subject to flash floods during the rainy season.

(2) *Mountainous and Hilland*. In the middle of the study area are the Al Mountains (Golis Mountains), oriented almost E-W parallel to the coast, with a very rugged topography rising to more than 1500m asl. Both sides of the mountains, towards the sea and southern hinterland, are drained by numerous streams of varying sizes.

(3) *Plateau*. Large, gently undulating and almost flat highlands and plateaus south of the Al Mountains, varying in altitude between 1500 - 1900m asl and cut by several streams (called Togga, Tug or Wadi).

According to the Sogreah soil survey report [2], patterns of soil distribution closely follow the geomorphology of the region. On the high plateau, soils were mapped as predominantly deep and heavy textured Vertisols. The Mountainous and Hilland area were mapped as rocky, or covered by shallow Entisols and some Aridisols. The soils in the Piedmont areas were classed as Entisols and Aridisols. A big portion of the region is covered by Rocky soils that were mapped as a separate non soil class.

2.5 Land cover

The land cover of the study area consists mostly of natural vegetation. Land cover classes include Open Shrubs, Open Trees and Open to Closed Herbaceous. Closed Trees are not common. Other cover types include Urban and Associated Areas (Settlement/Towns and Airport), Bare Areas (Bare Soils and Sandy areas) and Natural Waterbodies.

The main woody species in the study area include *Acacia nubica, A. tortilis, A. bussei, A. senegal, Aloe* spp*., Croton gilletti, Hypoestes hildebrandtii, Acalypha fruticosa, Grewia tenax,*and *Balanites aegyptiaca.* Common herbaceous species are *Cenchrus ciliaris, Cynodon dactylon, Sporobolus marginatus, Tragus racemosus* and *Aristida adscensionis*. More details on land cover and vegetation of the area can be found in FAO-SWALIM Technical Report No. L-03.

2.6 Land Use

The main land use in the study area is extensive grazing (pastoralism). Other land uses include rainfed agriculture, irrigated orchards along alluvial plains, and wood collection.

Rainfed agriculture is found in what is considered as the sorghum belt of Somaliland, practiced in combination with pastoralism and wood collection. This class of land use is the economic basis of households in the study area.

Cultivation of irrigated orchards is a cash-oriented activity in the area, involving the growing of fruit trees such as citrus, guava, papaya and mango. Supplementary water for irrigating the crops is obtained from wells, dams and other water bodies.

Wood collection for charcoal production is very frequent, occurring in all well-treed areas. Preferred tree species are *Acacia bussei, A. nilotica* and *A. etbaica.* Interventions to help introduce sustainable sources of cooking energy are important and urgent.

Most of the area is used for extensive grazing, or pastoralism. Goats and sheep are grazed mostly on sloping areas, whereas cattle and camels are grazed in flatter areas. Sedentary pastoralism around homesteads is a common practice. Hay harvesting from enclosures supports this land use, as harvested hay can be used in the dry season. However, hay harvesting may be a source of conflict as enclosures are not generally welcomed. Hay production requires further research to establish its levels of sustainability without being a cause of conflict in the study area.

Urban centers offer a good market for farm produce, but due to poor access roads are inaccessible to most farmers. The urban centers are also points of high demand for charcoal.

2.7 Population

The study area consists of the districts of Dila, Gebiley, Faraweyne and Allaybaday, and parts of the districts of Hargeisa, Borama, Baki and Lughaya. The size of the study area is slightly more than one third of the total area of Awdal and Waqooyi Galbeed Regions.

According to Somalia UNDP 2005 (Table 1), the estimated urban and non-urban population for Hargeisa by mid-2005 was 560 028, making it the second most populated town in Somalia. Borama had a population of 215 616 and Gebiley 79 564 inhabitants. These three centres are the main towns in the study area.

Table 2: Regions, districts, and their populations (Somalia UNDP 2005, draft version)

		District	**Estimated population**		
Zone	**Region**	**(* Regional capital)**	**2005 (Mid-year)**		
			Total	**Urban**	***Non-urban***
North-west			**1,828,739**	**819,989**	**1,008,750**
	Awdal		**305,455**	**110,942**	**194,513**
		Borama *	215,616	82,921	132,695
		Baki	25,500	8,577	16,923
		Lughaye	36,104	14,010	22,094
		Zeylac	28,235	5,434	22,801
	Woqooyi Galbeed		**700,345**	**490,432**	**209,913**
		Hargeisa *	560,028	422,515	137,513
		Berbera	60,753	42,070	18,683
		Gebiley	79,564	25,847	53,717

3 MATERIALS AND METHODS

3.1 Materials

The basic materials used in this work are given in Table2:

Table 2: Materials

TYPE	MATERIAL
Literature	Project reports Classification key WRB 2006 Thematic maps
Hardware	Soil survey tools Soil laboratory equipment
Software	ArcGIS 9.0 ILWIS 3.3 ArcViews 3.2 SDBmPlus 2.01 NSM Microsoft Excel 2000

3.2 Methods

3.2.1 Bibliographic research and data collection

A complete bibliographic research of principal sources such as reports, internet, grey literature, scientific articles, etc. was performed regarding all soil survey activities carried out in the study area. The SOGREAH study [2] was the primary source of data on soils in the study area. However, attempts to collect data on soil profiles, soil descriptions and soil maps, revealed their unavailability. The soil survey report contains general information about soils, but no map. Some soil profile descriptions were available, but were without coordinates.

3.2.2 The soil mapping model

According to Heuvelink [4], soil spatial variability can be described by two types of models: a discrete model of spatial variation (DMSV), and a continuous model of spatial variation (CMSV). Traditionally, conventional soil surveys follow the discrete model of spatial variation, which produces a polygon type or entity map.

Conventional soil surveys, including mapping activities, should follow standards for scale and sampling intensity, According to Avery and Dent [5, 6] if the objective is to produce a map at scales of 1:50 000 and 1:100 000, the following rules should apply:

At 1:50 000 scale

Medium semi-detailed soil survey, general purpose
Inspection density according to Avery and Dent: 1 per 0.2 km^2 (20 ha) to 1 km^2 (100 ha)
Area of study: 12.936 km^2
Considering the optimum and the area characteristics:

1 sample - 0.2 km^2
X - 12 936 km^2
X = 64684 samples

Considering the minimum and the area characteristics:

1 sample - 1 km^2

X - 12 936 km^2
X = 12936 samples

At 1:100 000 scale

Low semi-detailed soil survey, resource inventory
Inspection density according to Avery and Dent: 1 km^2 (100 ha) to 4 km^2 (400 ha)
Area of study: 12.936 km^2
Considering the optimum and the area characteristics:

1 sample - 1 km^2
X - 12 936 km^2
X = 12 936 samples

Considering the minimum and the area characteristics:

1 sample - 4 km^2
X - 12 936 km^2
X = 3 234 samples

As we can see, a high level of soil sampling is required in order to follow a conventional survey based on determination of relationships between soils and landscapes.

Constraints in this area of interest included poor accessibility (few roads), the mountainous landscape, security restrictions due to the current socio-political situation and the presence of unmapped landmines, hence it was not technically or practically feasible to perform a conventional soil survey. Instead, alternatives had to be considered in order to perform the primary objective of soil mapping. Project constraints demanded the use of rapid automated techniques, combined with relatively time-intensive techniques such as Soil Inference Systems, limited field observation and sampling.

As mentioned by Scull [7], today there are many new methods that aim to improve soil mapping activities in areas with low spatial data infrastructure. These methods are known as DSM (digital soil mapping techniques) [8]. One tool is Predictive Soil Mapping, which infers soil classes based on low soil samples using an inference system relying on expert knowledge.

For the purpose of this study, we adopted the SoLIM (Soil-Land Inference Model) concept [9], which is a predictive soil mapping approach based on a soil-landscape model concept. This contends that soils are predictable when local environmental conditions and soil relationships to these environmental conditions are known. This approach includes use of dedicated software, SoLIM 4.0 [10], which was not used due to the extent of the study area and the lack of certain important data components.

Theoretical background of the model

The State Factor (soil-forming factors) forms the theoretical basis of Predictive Soil Mapping, as well as the traditional soil survey. This is based on the equation of soil forming factors by Jenny [11], who formalised the ideas of Dokuchaev regarding soil formation:

$$\mathbf{S} = F(Cl, O, R, P, T, \ldots..)$$

Where:

S = the formed soil
Cl= Climate
O = Organisms (fauna, flora, human activity)
R = Relief (geomorphology context)
P = Parent material or lithology
T = Time

This equation and theory states that soil profiles found in a given landscape are a function of climate, organisms, relief, parent material and time. This implies that if the spatial distribution of soil forming factors is known, the soil character may be inferred.

We consider two important issues here:

- Wherever soil is present, its presence is due to the combination of soil forming factors. However, specific environmental conditions determine specific soil forming processes because soil forming factors are permanent or constant in the environment.

- The predictive model should try to identify specific soil forming factors and processes acting in the landscape and leading to specific soil formation.

The Inference Model

The model comprises a combination of Expert Systems [12] and Decision Tree Analysis [13].

An expert system consists of: data (information on spatial environmental variables, e.g. climate, landform, etc.), a knowledge base (rules and facts relating to soil variation supplied by an expert, in this case the soil surveyor), and an inference engine (which combines data and the knowledge base to infer logically valid conclusions) [14].

The overall aim of the Decision Tree Analysis is to design a set of predictive rules (e.g. if geology type = A, then soil type = B) developed from training data, which can then be applied to a geographic database to predict the value of a response variable [15].

Our conceptual base consists of the theoretical background of the SoLIM (Soil-Land Inference Model) for the model itself, and the Jenny equation as the general rule for determining the distribution of soil classes.

The following equation corresponds to a contextualized version of the Jenny equation which will guide some of the inference model.

$$\text{SOIL A}\,(b) = f\,(\text{CL}(b)+\text{R}(b)+\text{P}(b)+\text{O}(b)+\text{T}(b))$$

This equation infers that the SOIL A situated in the environment *(b)* is there due to the combination of the principal soil forming factors under the specific environment B which generates specific soil forming processes A-B.

In this regard, the climate factor refers to specific climatic variables acting in that environment *(b)*.

The relief under which all the process are carried out corresponds specifically to the environment *(b).*

The parent material represents the initial material on *(b*), which after some processes have acted upon it will become soil.

The organisms present in environment *(b)* determine many activities acting on its attributes.

Finally, time or age is a very difficult, non-local factor. However, the initial equation relates to soil maturity, a factor that can be assessed in the field through horizon differentiation. In this study the time factor was not considered due to the primary objective being to infer which kind of soils were present in the study area. The geological

time can indirectly represent the soil time forming factor because it shows age of the different rocks.

Components

Data: the different data layers necessary to model the soil-landscape relationship. This corresponds to all the soil forming factors and specific spatial components collected in the field having a direct influence on soil spatial variability.

Expert Knowledge: this component values the knowledge of a soil scientist of the study area which, based on spatial data layers and fieldwork stage characterised the specific environment where each class of soil was developed. Based on those models and this expert knowledge, decision trees were constructed where predictive rules regarding soil formation were specified.

Inference engine: our inference engine was based on the use of ILWIS 3.1 and ArcGis 9.0. softare packages, together with the decision trees. As established by many authors [7], most of the Predictive Soil Mapping work was carried out in small areas in great detail and in far fewer larger areas on a smaller scale.

3.2.3 Landscape stratification (Geopedological approach)

The core of the overall approach was identification and understanding of the soil-landscape model concept. Landscape stratification was performed by adapting the Geopedological (GP) approach [16] to Somalian conditions. The GP approach is an hierarchical system which stratifies terrain from a geomorphological perspective, but with the objective of determining soil formations. This approach utilises six different categorical levels; however, only Landscape, Relief, Lithology and Landform levels were used. The present exercise started from an integrated and modified GP approach. The primary difference lay in the fact that, instead of aiming at producing a soil map using aerial photography (as in a conventional soil survey), the aim was a landform map, using satellite imagery. Spatial and spectral information extracted from an aerial photograph or a satellite image are quite different, even though they can be complementary. In addition, visual image interpretation was integrated with Digital Terrain Analysis, giving rise to integrated landform maps at 1:100 000 and 1:50 000 scales which were verified in the field.

The present approach has been called the Somalia Integrated Hierarchical Landform Mapping Approach – SIHLMA. For a detailed explanation of the procedure and the results, please refer to the Landform Mapping of Somalia Report [17] which is part of the land resources inventory of the SWALIM project carried out in the study area.

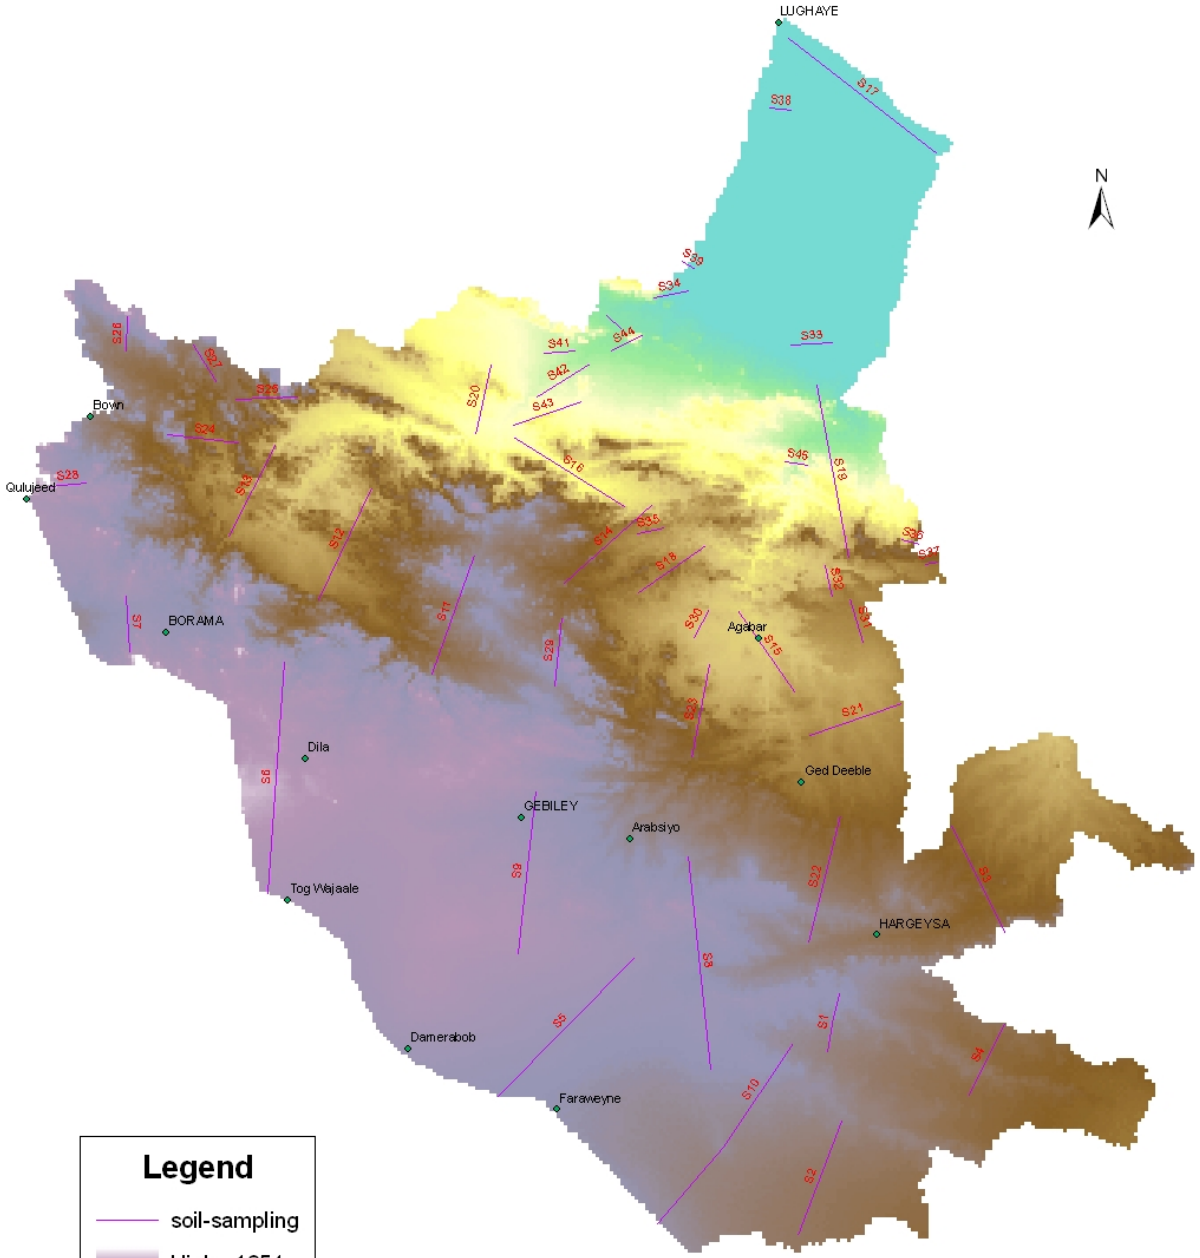
3.2.4 Soil sampling design

Considering the aforementioned constraints and the proposed model of the soil mapping activity, a soil sampling scheme was designed that would consider representative sites that would reveal the spectrum of soil spatial variability.

Using the produced landscape map, variability of different landscapes and relief types were analysed as well as their relation to soil formation, thereby assessing spatial variability and composition of the terrain component.

Referring to the representative landscapes and relief types, the accessibility map, security measures and presence of landmines, a Transect Sampling Scheme (Map 1) was designed that focused field soil data collection on representative sites. Transect locations represent sites where the soil-landscape model concept corresponded with areas of high soil variability.

MAP 1: Soil Transects Location



3.2.5 Soil field-survey

A field-based natural resources inventory was carried out by SWALIM between April and July 2006 in fulfilment of its main objective of land suitability assessment of the Dur-Dur and Gebiley catchments, which included a specific soil survey aimed at collecting soil data.

To support and guide important field activities, the SWALIM land team produced a Field Survey Manual [18].

Conventional soil profile descriptions were carried out along the different relief types found in each planned soil transect. Not all planned soil transects were visited, either due to impeded accessibility or presence of landmines.

At each site, a standard soil pit was dug. A soil collection form was designed to collect site information, soil attributes and pedogenetic indicators (see Annex 1). Physical and chemical soil properties were described for each soil profile and soil samples were taken for laboratory analysis in Nairobi, Kenya. A preliminary soil classification was performed using the WRB 98 soil classification system [19]. Augering was performed in areas where there was the need to definine boundaries between different soil classes.

Sites with rocky or stony soils were not described in detail, but a preliminary classification was still made.

3.2.6 Soil data input

Due to logistics between Hargeisa (Somalia) and Nairobi (Kenya) where the SWALIM office is located, completed soil forms were sent to Nairobi on a weekly basis.

All soil forms were entered into the soil profile database software SDBmPlus 2.1 [20], which is a specialised program for storing soil profile data. Once all soil profiles were entered, use was made of the program's capabilities to display the different soil profiles, the results of which may be seen in Appendix 3.

The software also allowed exportation of all data into a point based soil geographic database . This database was stored as a Microsoft Access file. It should be remembered that an area-class map where this kind of database is very useful, was not produced.

3.2.7 Soil Laboratory analysis

A sample of 500g of soil was collected from each horizon for soil analysis. All soil samples collected in the field were sent to Nairobi on a weekly basis repeat of above. Soil samples were analysed in the KARI (Kenya Agriculture Research Institute) Soil Laboratory following a standard soil analysis. Parameters analysed and methods used were:

<u>Soil texture</u>

Particle-size analysis was done using the Bouyoucos hydrometer method, where A 50g soil sample was placed in a plastic shaking bottle with 50mls calgon dispersion agent. A blank (without soil) sample was also prepared. These were shaken overnight, transferred into sedimentation cylinders and topped up to the 1000 ml mark. The mixture was well stirred using a metal plunger to bring the particles into suspension. A soil hydrometer was used to take readings after 40 seconds and two hours, respectively. The second reading gave the clay content and was calculated as follows:

% Clay = (R2-Rb)/50*100

The first Reading gives the Silt + Clay

which is

% (Silt + Clay) = R1/50*100

%Silt is therefore this reading minus %Clay

% Sand is 100 – % (Silt+Clay)

After determining percentages of sand, silt and clay, a textural classification chart (see below) was used to classify the soil.

Dry Soil Bulk density
Only the first horizon for all the profiles was analysed. Bulk density is best estimated by a core-sampling method. However, undisturbed soil samples were unobtainable so dry bulk density was estimated as follows: Dry the soil in the oven and let it cool. Pour sample into a plastic cylinder. Let the cylinder drop from a height of 5-30 cm for 50 taps. Read the volume and weigh to determine the weight of the soil. The weight of the soil divided by the volume gives the bulk density.

Extractable Phosphorus
The Olsen method was used for this purpose. Dried soil samples were extracted in a1:5 ratio (w/v) with 0.5M sodium bicarbonate solution at pH 8.5. Phosphorus in the extract was determined spectrophotometrically.

Soil pH and EC
Soil pH and EC were determined in a 1:2:5 (w/v) soil- water suspension, using a pH meter and conductivity meter respectively.

Total organic carbon
The calorimetric method was used to determine this important property. All organic carbon in the soil sample was oxidized by acidified dichromate at 150°C for 30 minutes to ensure complete oxidation. Barium chloride was added to the cool digests. After thorough mixing, digests were allowed to stand overnight. Total C was determined spectrophotometrically.

Total Nitrogen
The Kjeldahl method was used for this purpose. Soil samples were digested with concentrated sulphuric acid containing potassium sulphate, selenium and copper sulphate hydrated at approximately 350°C. Total N was determined calorimetrically on a flow analyser.

Cation Exchange Capacity and Exchangeable Ca, Mg, K, Na
Soil samples were leached with 1N ammonium acetate buffered at pH 7. Leachate was analysed for exchangeable Ca, Mg, K and Na. Sample were further leached with 1N KCl, and leachate used for determination of the CEC. Elements such as Na and K were determined with a flame photometer and Ca and Mg with AAS (atomic absorption spectrophotometer). CEC was determined calorimetrically on a flow analszer.

Once soil laboratory results were available, they were integrated into the general database in the SDBmPlus 2.1 software which was used to construct the final soil profile database.

The samples were also sent to ICRAF where they were scanned for spectral reflectance. The results of this analysis can later be used for land degradation assessment.

3.2.8 Soil classification

All soil profiles were preliminarily classified in the field using the WRB 1998 [19]. Once soil laboratory results were available, soil profiles were classified using the new WRB soil

classification system v.2006 [21]. Soils were classified at two levels: at reference group, and prefix and suffix levels. Once this was done, some key soil profiles were sent for revision in terms of classification to ISRIC (Dr. Otto Spaargaren).

3.2.9 Determination and acquisition of necessary environmental variables

The SWALIM land team have generated different thematic layers, mainly as landscape, relief, land cover and land use maps. All are considered important soil forming factors which later were used in the soil modelling process. Some other layers like Soil Moisture Regime and Slope maps were generated using different approaches. All the maps used the same geodesic system, that can be found in Table 4.

Table 4: Geodesic System

GEODESIC SYSTEM	PARAMETERS
Projection	Universal Transversal Mercator (UTM)
Datum	WGS 1984
Ellipsoid	WGS 1984
Zone	38

The different environmental variables that were generated can be found in Table 5:

Table 5: Environmental variables

VARIABLE	DATA TYPE	LEVEL OF DETAIL IN THE SOILS PREDICTION
Landscape	Discrete	General at Reference group (WRB)
Soil Moisture Regime	Continuous	General at Reference group (WRB)
Lithology	Discrete	General at Reference group (WRB)
Land use	Discrete	At prefix level (WRB)
Land cover	Discrete	At prefix level (WRB)
Relief	Discrete	At suffix level (WRB)
Slope	Continuous	At suffix level (WRB)

Landscape and relief maps

Maps mentioned in para 2.3.3 were generated using the GP approach. Project Report L-02 should be consulted for a detailed explanation on procedures and results. Maps 2 and 3 show landscape and relief types in the study area, and Table 6 contains a detailed legend.

Land cover map

This map was generated by the SWALIM team using the LCCS classification system for legend production, and satellite image interpretation combined with fieldwork verification. For a detailed explanation of the land cover refer to Project Report L-03 and Map 4

Land use map

This map was generated by the SWALIM team using the land cover map as the cartographic basis, and a land use field survey using semi-structured interviews. For a detailed explanation of the land cover refer to Project Report L-04 and Map 5.

Slope map

The slope map was produced using the corrected SRTM Digital Elevation Model. The surface spatial analyst extension of Arc GIS 9.0 was used to derive slope classes according to variability in the area. The slope classes used can be found in Table 7. Map 6 shows slope distribution in the study area.

Table 7: Slope classes

SLOPE CLASS	RANGE %
1	0-3
2	3-8
3	8-15
4	15-25
5	25-40
6	40-65
7	65-100

Soil moisture regime map

Soil moisture and temperature regimes in the area were calculated using climatic data that was entered into the NSM (Newhall Simulation Model) software package [22]. Once the soil moisture regime for each climatic station was obtained, the values were interpolated using ILWIS 3.3. software and incorporating the DEM as a correlation factor. This was not performed for the soil temperature regime due to low variability. The

different soil moisture regimes and temperature regimes can be found in Table 8 and the soil moisture regime for the area can be seen in Map 7.

Table 8: Soil moisture and temperature regimes

STATION	MOISTURE REGIME	TEMPERATURE REGIME	DRY-D/M-MOIST	TENTATIVE SUB-DIVISION
Hargeisa	Aridic	Isohyperthermic	290-70-0	Typic Aridic
Gebiley	Aridic	Isohyperthermic	258-102-0	Typic Aridic
Borama	Aridic	Isohyperthermic	250-110-0	Weak Aridic
Berbera	Aridic	Isohyperthermic	360-0-0	Extreme Aridic
Burao	Aridic	Isohyperthermic	345-15-0	Typic Aridic
Shiekh	Aridic	Isothermic	213-147-0	Weak Aridic

Soil Temperature Regimes

Isothermic
The mean annual soil temperature is 15°C or higher but lower than 22°C.

Isohyperthermic
The mean annual soil temperature is 22°C or higher, and the difference between mean summer and mean winter soil temperature is less than 5°C at a depth of 50 cm.

Soil Moisture Regimes

Aridic
The soil moisture control section is, in normal years:

- Dry in all parts for more than half of the cumulative days per year when the soil temperature at a depth of 50 cm from the soil surface is above 5°C; and
- Moist in some or all parts for less than 90 consecutive days when the soil temperature at a depth of 50 cm is above 8°C.

Extreme Aridic
The soil moisture control section is always completely dry. Cultivation is not possible without irrigation.

Typic Aridic
The soil moisture control section is moist in some or all parts at same time in the year for 45 consecutive days or less when the soil temperature at 50 cm depth is more than 8°C. Cultivation is not possible without irrigation.

Weak Aridic
The soil moisture control section is moist in some or all parts at same time in the year for 45 consecutive days or more when the soil temperature at 50 cm depth is more than 8°C. Cultivation is possible without irrigation for a short period.

3.2.10 Development of a key to separate soil classes based on environmental variables

Taking into consideration the geographic context of the study area, there is a theoretical soil genesis that has determined the soil classes that can occur there. Overall soil patterns can be understood using the soil-landscape model. However, it was important to develop a key that is able to establish or predict soil type occurrences using the different soil environmental attributes generated previously.

The development of this key is the core behind this model, as it characterises the environment where each individual soil class might be formed.

An example of the key can be found below in Figure 5.

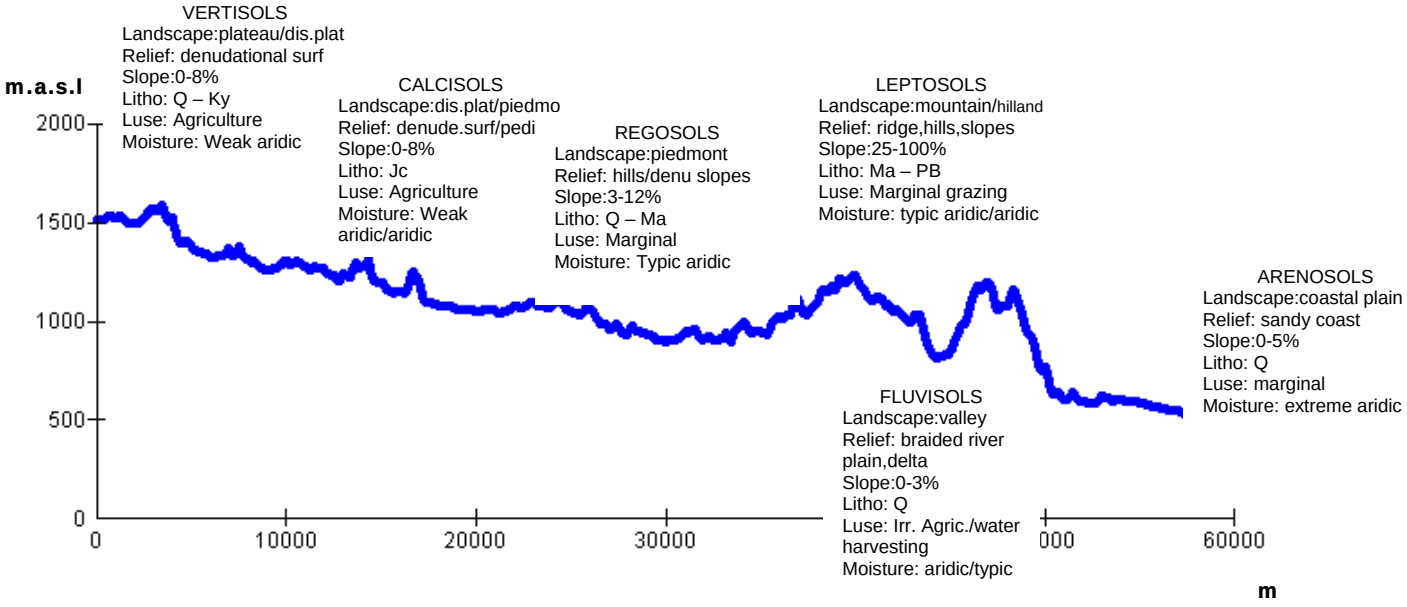

Figure 5: Soil-environmental characterisation

This key was later used to create different decision trees to infer or predict the occurrence of each soil class in a specific geographic position where the environmental characteristics are met.

3.2.11 Characterisation of soil classes (decision tree)

The aim of the decision trees was to design a set of predictive rules, using available data layers to guide the process of prediction or inference of the different soil classes in the study area according to its geographic patterns. These predictive rules were obtained using the key developed previously, where the environmental conditions where each soil class should be found were established. The general decision tree can be observed in Figure 6. and can be read it conditionally from column one and generating the last column where the soil class is expected under those specific environmental variables.

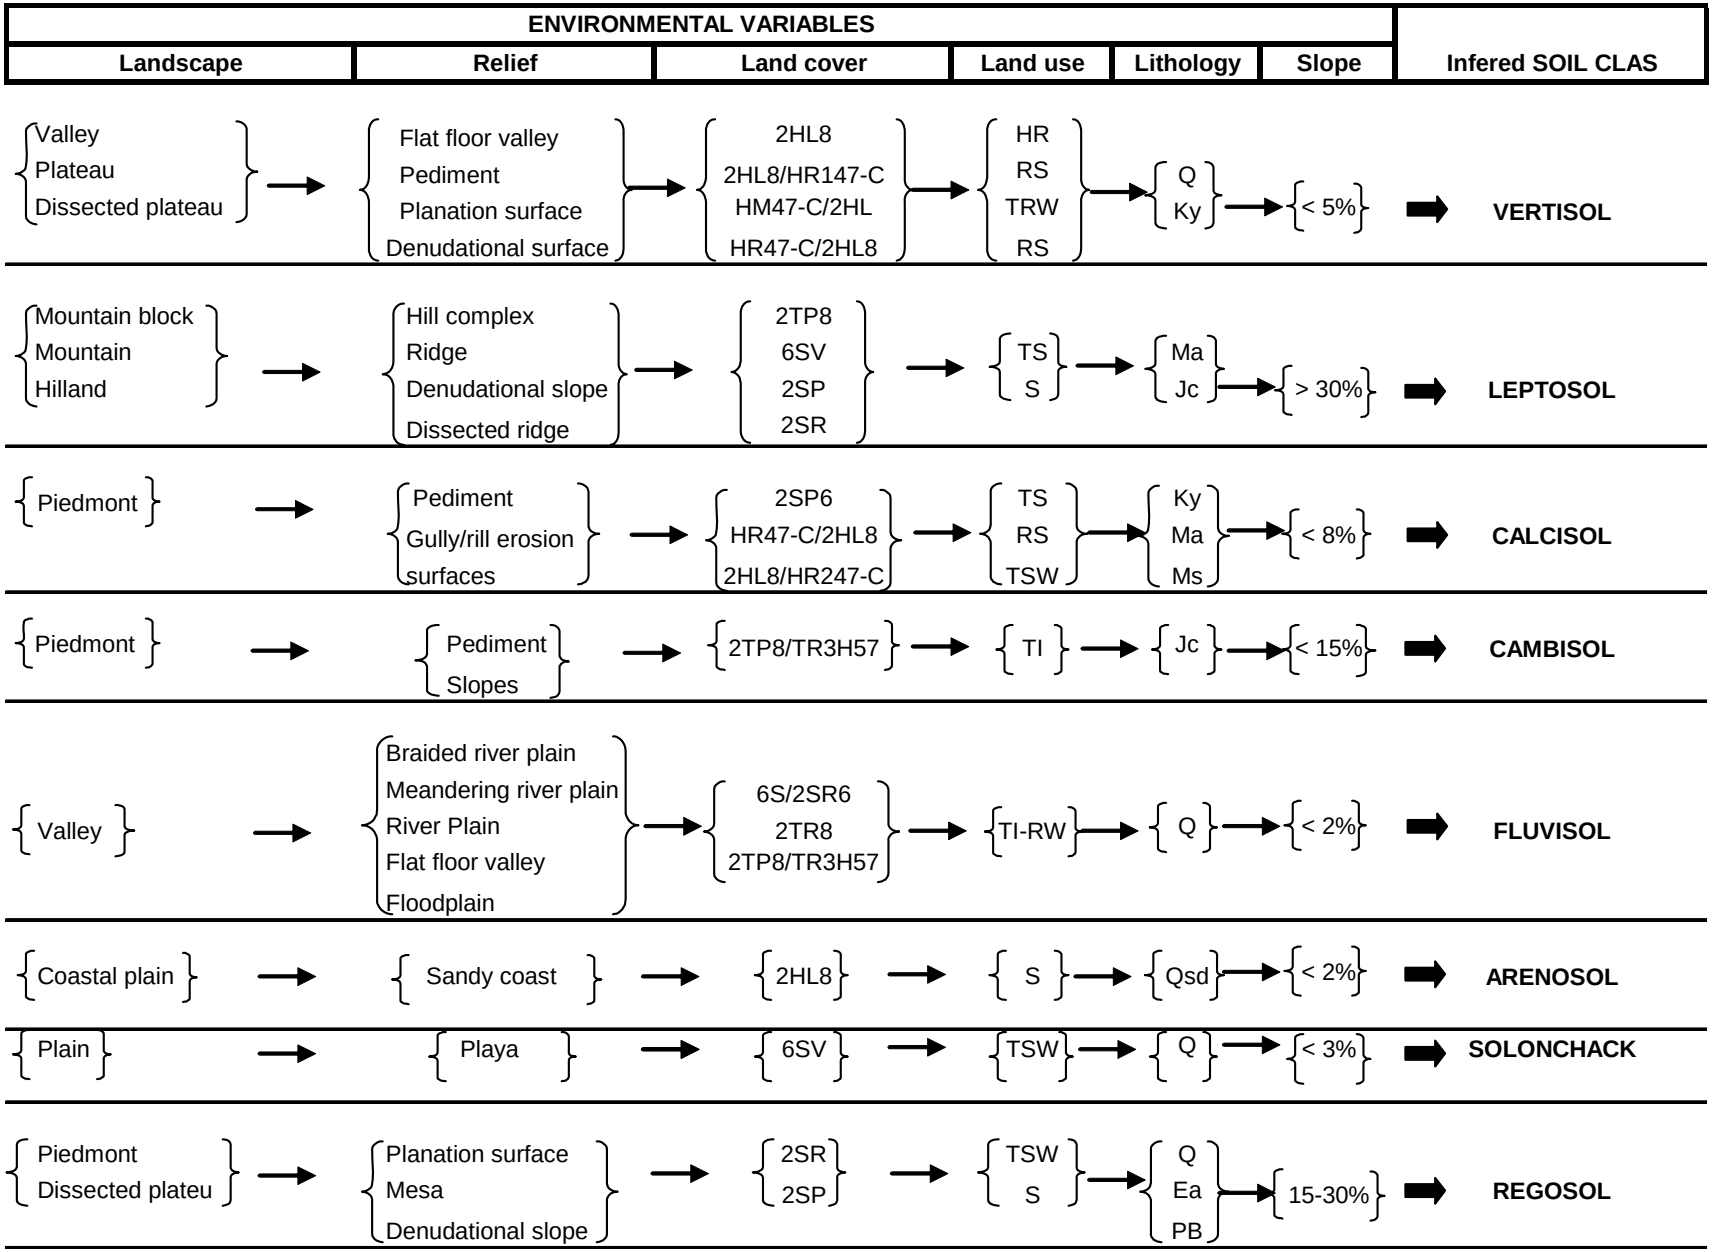

Figure 6: Decision tree

3.2.12 Running the soil prediction model

The prediction model was run using ILWIS 3.3 software. All decision trees created in the previous step were written using Map Calculation formulas into a spatial analysis process.

The model was run twice, according to the two different map scales (1:100.000 and 1:50.000) produced.

An example of the written formulas in the Map Calculation format can be found next:

At 1:100.000

Soil2=iff((lands="Pta")and(relief="S32")and(lc="2SP7/HM147-C") and(luse="TRW")and(Litho=”Ky”), "calcic vertisol", soil1)

At 1:50.000

Soil2=iff((lands="Vay")and(relief="F14")and(lc="2HL/HR147-C") and(luse="HR")and(Litho=”Q”),and (Slope=”1”)and(Moisture=”3”),”b”, soil1)

b=Calcic Grumic Vertisol (Hyposodic, Chromic)

After running all formulas for both map scales, a raster map was produced and exported into a standard format compatible with the Geodataset developed by SWALIM for storing the different data layers. This map was subjected to verification and validation through quality assessment and improvement.

3.2.13 Verification and validation of the soil maps

When producing thematic maps, it is important to indicate accuracy levels for the benefit of users. Verification and validation procedures were applied to the two soil maps produced (at 1:100.00 and 1:50.000), using two different approaches that share the same principle.

Firstly, a *verification process* based mainly on the expert knowledge [10] of a soil scientist familiar with the study area, was conducted. This process involved two steps: a) a reviewed of overall soil patterns of the inferred soil map to determine any mismatches according to the scientist’s own soil-landscape model (which was the main mapping concept). b) After reviewing the overall pattern, a soil scientist evaluated specific knowledge on soil classes, especially in transitional areas where he has field knowledge. This step was done generating random points distributed throughout the study area, through the use of Random Point Generator, an ArcView extension developed by Jenness [23]. The soil scientist then applied his expert knowledge to each random point and compared the inferred soil class with his knowledge of that specific point according to environmental variables forming that specific soil class. An error matrix was produced showing mismatches.

Secondly, a validation process based on field soil profiles collected during the field survey was performed. This involved a similar process of comparison, differing in comparison of observed soil classes in the field and those that were inferred. Similarly, an error matrix was produced showing mismatches between soil classes. A general accuracy for the map was produced using data produced by the error matrix.

Once the verification and validation process was performed, we corrected the main anomalies or mismatches of the prediction system, mainly related to the decision tree, so, we have adjusted the decision tree for some specific cases.

4 RESULTS

4.1 Soil profiles

Eighty-two soil profiles were described in the course of this soil survey. Fifty out of the 82 profiles were completely described, including both site and profile descriptions, and soil samples being sent for chemical and physical analyses. The remaining 32 profiles consisted only of site descriptions due to their rocky and stony characteristics that did not allow digging of profiles and subsequent description. Soil classification was however possible.

All profiles and site descriptions were classified using WRB 2006 and stored in a soils database. Complete soil descriptions can be found in Appendix 3. Map 8 shows the distribution of the 82 profiles in the study area.

4.2 Soil map at 1:100 000 scale

A 1:100 000 soil map (Map 9) of the whole study area was produced using the Reference Soil Groups level and Prefix qualifier level of the WRB 2006 classification system. Soils encountered were mainly Vertisols, Leptosols, Regosols, Calcisols, Fluvisols, Arenosols, Cambisols and Solonchaks. Soils extent and distribution as shown in Map 9 is as follows (Table 9):

Table 9: Area of soil reference classes and key properties

Class (Reference Group)	Km²	%	Key properties
Vertisols			Soils influenced by water; alternating wet-dry conditions, rich in swelling clays.
Calcic Grumic Vertisol	1252	22.9	
Calcic Mazic Vertisol	97		
Calcic Vertisol	1440		
Haplic Vertisol	170		
Fluvisols			Soils influenced by water; floodplains, valleys, marshes
Calcic Endosalic Fluvisol	117	15.1	
Calcic Fluvisol	47		
Haplic Fluvisol	771		
Haplic Fluvisol (Skeletic)	1020		
Calcisols			Soils with accumulation of calcium carbonate.
Endosalic Calcisol	49	9.1	
Haplic Calcisol	558		
Hypercalcic Calcisol	46		
Luvic Calcisol	120		
Petric Calcisol	27		
Vertic Calcisol	368		
Vertic Petric Calcisol	11		
Cambisols			Moderately developed soils.
Fluvic Cambisol	432	3.3	
Arenosols			Sandy soils located in coastal plains.
Haplic Arenosol	89	0.7	
Leptosols			Shallow or extremely gravelly soils.
Haplic Leptosol	216	38.6	
Haplic Leptosol (Skeletic)	304		
Haplic Leptosol (Skeletic)/Haplic Regosol	200		
Hyperskeletic Leptosol	1093		
Hyperskeletic Lithic Leptosol	1392		
Lithic Leptosol	1097		
Hyperskeletic Lithic Leptosol/Haplic Regosol	230		
Hyperskeletic Lithic Leptosol/Haplic Regosol (Skeletic)	462		
Solonchaks			Soils with salt enrichment upon evaporation.
Haplic Solonchak	25	0.2	
Regosols			Soils with no significant profile development.
Haplic Regosol	967	7.5	
Haplic Regosol (Skeletic)	287	2.2	
Haplic Regosol/Haplic Calcisol			
Technosols	49	0.4	Urban soils in the main towns: Hargeisa, Gebiley and Borama.
Total	**12934**	**100**	

The dominant soils in the study area are Leptosols and Regosols. Difficulties were encountered in separating them due to limited field data in this inaccessible area, as well as them sharing some common characteristics.

The second-most dominant soils are the Vertisols, found mainly in agropastoral areas of the area of interest. The Fluvisols are also present, in a considerable extension located mainly in the fluvial system of the area of interest. A considerable amount of Calcisols and Cambisols are also found, which are characteristic soils of the **environment** area?. Arenosols are respresented in a very small area in the coastal region of the area of interest and Solonchaks which are found in the *playas* in the southern part of the area of interest. The Technosols, corresponding to the main urban areas, were not studied in detail, so were kept at the reference group level in WRB 2006.

4.2.1 Technical description of the soil classes

Vertisols (Profiles 101, 109, 122, 125, 303, 305, 307, 309, 306, 308, 323, 329, 117, 121, 301, 120, 123, 302, 325, 316, 328, 102, 304, 321, 326)

Vertisols occur in the Plateau and dissected plateau between Hargeisa, Gebiley and Borama, south of the Al Mountains. The plateau is mostly flat apart from areas of uneven relief, slopes towards streams and rolling surfaces. From a climatic point of view this area is considered as semi-arid due to its higher annual rainfall of 500 mm in comparison to the rest of the study area; this situation positively influences soil formation processes. These soils are located in the unique agro-pastoral system of the study area commonly called the “sorghum belt”. Many water-harvesting techniques hva ebeen and are applied in this area, which in some cases were poorly designed and are causing gully and rill soil erosion.

Vertisols are churning, deep heavy clay soils with a high proportion of swelling clays. These soils form deep, wide cracks from the surface downward to more than 50 cm below the surface when they dry out, which happens in most years. These cracks are not always well represented on the surface due to them filling with sand.

Vertisols are fine-textured soils dominated by expanding montmorillonite clay minerals. The minerals normally expand and contract on wetting and drying, respectively. In the dry condition the soils develop a shallow grumic or granular mulch structure and form wide cracks on the surface. The cracks extend vertically separating blocky and prismatic structures. Some of the mulch falls or is washed into the cracks during rains so that this causes a mix up effect in the whole profile in the alternating wetting and drying when expansion pressure happens in the lower horizon. The effect of the pressure develops slip-faces (slickensides) and wedge shaped structure in the lower horizons and often to gilgai micro-relief at the surface. The soil becomes plastic and sticky when wet and the cracks close. The soils become very hard when dry.

The Vertisols in the study area generally contain more than 35% clay increasing with depth, and they fall exclusively into the clay classes (see Table 10). Parent materials are mostly sediments that contain a high proportion of swelling clays, or products of rock weathering that have the characteristics of swelling clays. The soil structure of these vertisols is largely influenced by prevailing soil moisture content, which is demonstrated in dry conditions where the soils are often very hard except for the top 10 - 20 cm where there is natural, friable self-mulching layer.

Table 10: Soil laboratory results of the Vertisols

The Vertisols in the study area have low stable porosity, and a predominance of fine pores. The topography is usually flat or gently sloping throughout the alluvial plain, and the most common soil erosion type is slight sheet wash, but rill and gully erosion occur on the upper slope of the dissected plateaus around the Borama/Gebiley catchments.

A Gilgai microrelief is often a peculiar sign of the Vertisols; in this study this feature was not found, although many sinkholes were observed.

Soil physical properties

The bulk density of the vertisols in the study area can be broadly characterised as available data is limited to the surface horizons and it is recognised that clay content increases with soil depth. Bulk densities are usually very widely distributed and occur in a moderately low range between 1.16 - 1.54g/cm^3. These variations are caused by swelling and shrinking with changes in soil moisture content. Bulk density is high when the soils are dry and low when wet. Water infiltration is moderately slow.

In the dry season, surface horizons are characterised by grumic and granular structure (forming surface mulch) at intervals of 10 - 20 cm which often cover up wide, deep vertical cracks in the soil. In the subsoil there are strongly developed prismatic, angular to sub-angular structures separated from each other by cracks of various sizes. In the wet season all the structures are almost completely destroyed, reducing the surface horizon to a massive block. Shiny pressure faces and/or well-developed slickensides were also observed in the profiles. Porosity is limited, except for the cracks developed during the dry season and occasional root channels. In the lower horizons the plant roots are confined to cracks and slickenside faces.

The vertisols in the study area have a relatively high water storage capacity in the root zone of the upper 1m of the soil profile, due to their depth and high clay content. The soil moisture content in the deeper layers is lower, apparently due to compression effects on metric potential. As this study area is characterised by uncertain rainfall, the water stored in the soil profile is very important for survival of crops during the growing season until the end of the rainy season.

Soil chemical properties

In an arid and semi-arid climate it is recognised that the major chemical factors limiting crop production are usually related to the increase of soluble salts in the soil. Therefore attention is always focused on chemical analyses to assess the types and amount of soluble salts and amount of exchangeable sodium associated with the soil clay. Consequently, all the soil horizons of the sampled profiles were subjected to detailed chemical analyses.

Chemical analysis of vertisols in the study area (Table 10) show them to be rich in clay content, moderately alkaline in reaction and moderately base saturated (for the interpretation, see Annex 2). Salinity values are uniformly low throughout the soil profile. The levels of exchangeable sodium are generally very low. These characteristics are favourable for crop production.

Soil Fertility

The results of tests on organic matter and total nitrogen in the surface horizons of the soil profiles show values of less than 1% and 0.1% respectively, indicating that levels of organic matter and total nitrogen are lower than deficient. These low values are probably a result of the arid and semi-arid climates, but a major factor is also the lack of soil management practices in relation to the agricultural and pastoral systems. Therefore, nitrogen fertilizer will be necessary to maintain or increase crop yields under present farming systems.

Phosphorus (P) was determined to be the "available" form. The measured values of phosphorus indicate it is irregular in terms of content and distribution in almost all the profiles. Phosphorus values vary from site to site, and similarly downwards in the soil profile, ranging between 3.5 - 35.5 ppm. Rating of P according to guidelines for interpretation by Olsen's method (Landon, 1984) suggests that values < 5 ppm can be considered low and 5 - 15 ppm as medium. Values > 15 ppm are considered excessive. As pH values of soils in the study area are moderately alkaline to strongly alkaline, phosphorous is subject to fixation or formation of poorly soluble calcium phosphate, suggesting that application of phosphate fertilizer is required and likely to improve production in intensive cultivation systems.

Management and use
The vertisols in this semi-arid region are used for different purposes, but primarily for rain-fed agriculture through smallholder post-rainy season crop cultivation, mainly sorghum, maize, millet, cowpeas and Qat, and extensive grazing and wood collection.

Crop management practices are mainly directed towards building soil bunds for water harvesting, in combination with soil conservation in order to store more water in the soil. Neither manure nor mineral fertilizers are not applied to crops.

Fluvisols (Profiles: 103, 106, 107, 113, 200, 201, 206)
Fluvisols are young soils developed on parent material of recent alluvial plains, river fans and tidal marshes which are periodically flooded by seasonal rivers which are very common within the Al Mountains, Highlands and Dissected Plateaus, mostly in the central part of the study area. Soil profiles show stratification and a weak subsoil horizon differentiation due to successive flooding and deposition of soil material.

The climate is arid and semi-arid, similar to that of the Vertisols. Topography is a flat to gently undulating surface. The natural vegetation varies from general open trees with shrubs, sparse shrubs with a herbaceous layer, general open shrubs and bare soil. The fluvisols in the study area are very important because they are used for irrigated orchards along the alluvial plains of the main rivers and *toggas*.

Physical and chemical properties
In arid and semi-arid climates, it is recognised that the major physical and chemical factors limiting crop production usually relate to soil texture, alkalinity, sodicity and levels of salinity. Therefore, attention is always focused on physical and chemical analyses to assess important parameters associated with soil characteristics. Consequently, all soil horizons of the sampled profiles were physically and chemical analysed, and described as follows:

Fluvisols in the study area all have diverse texture classes which change within the soil profile and in different spatial areas. The majority of these soils have good water drainage and water holding capacities, and are periodically flooded. They have variable bulk density ranging from 1.30 - 1.67, which is fairly high. The pH ranges from moderately alkaline to strongly alkaline, varying with depth or spatially.

Salinity is not a major hazard in these soils. Results obtained from the analyses show that a limited number of sites' lower horizons have a moderate degree of salinity and may cause salinity problems in the long term if irrigation is applied to inadequately drained land.

The analytical value of the total sums of CEC in the fluvisols of the study areas are variable and range from low (5 - 15 meq/100g) to medium (15 - 25meq/100g) and with an irregular distribution within the profiles. This is due to the diverse nature of the stratification layers and their content of colloidal material clay and organic matter. The base saturation is high or moderate. The dominant exchangeable cations are calcium and

magnesium. There is no sodium hazard and the soils are strongly calcareous. All the fluvisols are deficient in organic carbon and nitrogen, and phosphorus values are also low. Available potassium is adequate. Application of organic manure or inorganic nitrogen can yield better crop responses in terms of yield.

Management and use
The fluvisols of the study area are developed in river plain landscapes and have good natural fertility. They are usually suitable for all uses, but in the project area are commonly used for irrigated crops or grazing and woodcutting for fuelwood.

Calcisols (Profiles: 110, 114, 115, 118, 119, 124, 129, 135, 136, 138, 310, 311, 317)
The calcisols are soils commonly developed in the study area and are characterised by having a substantial secondary accumulation of lime. They principally occur in dissected plateaux and some piedmonts of the study area. Deep fluvial incisions form areas of bare rock at the upper surface part of the landscape, generally causing high and intense degradation. They are developed in highly calcareous parent material mainly in the Fossiliferrous limestone and Yesomma sandstones. The parent material in the lower parts of the landscape is mostly alluvial and colluvial, consisting of base-rich weathered deposits consisting mainly of highly calcareous sands and gravel of colluvial and alluvial soil deposits.

The natural vegetation consists of general open shrubs with open herbaceous, sparse trees and different herbaceous cover. Most of these soil units are used for rainfed agriculture and livestock grazing.

Physical and chemical properties
The majority of the calcisols have a clayey texture which varies slightly with soil depth (see Table 11). These soils are strongly calcareous throughout the soil profiles, moderately alkaline to strongly alkaline, non saline, have adequate to high CEC, high to adequate or rarely excessive content of phosphorus and are deficient in organic matter and total nitrogen (for interpretation see Annex 2).

Management and use
The vast majority of the calcisols are under shrubs, grasses, herbs and sparse tree cover and are used for general grazing. Some calcisols are used for production of isolated rainfed fields of herbaceous crops (single or multiple), sorghum and maize where arable farming is not hindered by surface stoniness or a shallow petrocalcic horizon.

Cambisols (Profiles: 108)
These are soils with an initial stage of subsurface soil horizon differentiation. They occur in slopes, denudational surfaces and in some alluvial deposits in the study area. The parent material is derived from a wide variety of rocks, the most common of which is fossiliferous limestone. The profiles are characterised by slight transformation of the parent material and evidence changes in soil structure, colour and clay content, but there is an absence of appreciable quantities of illuviated clay or carbonate content, organic matter, Al and/or Fe compounds. The topography varies from flat to gently sloping surfaces of alluvial deposits.

The soils are covered by wide range vegetation from general open trees with shrubs, dense shrubs and herbaceous cover. The main use of these soils is for livestock grazing and in small cases for rainfed agriculture purposes.

Physical and chemical properties
Soil analysis data of cambisols examined in the project area show that soil texture is within loamy classes and of low bulk density. These soils are moderately alkaline in soil reaction, non saline to moderately saline, high to moderate CEC, high base saturation and strongly calcareous. They are deficient in nutrients, specifically nitrogen and phosphorus.

Management and use
Due to insufficient rainfall moisture conditions, these soils are commonly used for grazing and wood harvesting. Small irrigated fields of fruit trees and herbaceous crops (pulses and vegetables) are practiced beside the water sources.

Arenosols (Profile: 104)
The Arenosols comprise soils developed on the coastal plain, which is commonly flat with small, slightly sloping surfaces towards the Red Sea. The coastal plain is intersected by broad rivers forming deltas, accumulating seawards. Seasonal flush floods originating in the hills and Al Mountains occur in large parts of the area.

Parent material of soils in the coastal plain consist of mixed unconsolidated deposits from sandy aeolian beach deposits (consisting of quartz particles and mica flakes) with finer materials from loam to silty clay texture of recent alluvial deposits. The soil profile shows no sign of development or horizon differentiation.

Natural vegetation cover varies from bare soil with scattered vegetation, to general open herbaceous and closed strips of exotic trees (*Prosopsis* sp.) along the streams.

Physical and chemical properties
The arenosols of the study area have a loamy sand texture class and moderately high bulk density. This indicates that these soils are highly permeable and have low water storage capacity.

The soils are strongly alkaline in reaction, not saline, low in CEC and deficient in soil nutrients, particularly organic matter, nitrogen and phosphorus.

Management and use
The arenosols are found in the arid coastal plain where annual rainfall is lower than 150 mm. They are characterised by a common sandy class texture, high permeability and low water holding capacity, low nutrient storage and high sensitivity to wind erosion. They do not favour cultivation of crops. The most common land use is transhumance grazing and sedentary pastoralism. The most common grazing animals are goats and camels.

Leptosols (Profiles: 21, 22, 23, 24, 25, 27, 28, 29, 30, 31, 32, 33, 35, 37, 38, 39, 42, 46, 51)
Leptosols are the dominant soils in the study area, occurring mainly in the northern central part of the study area on the Al Mountains, but are also present in the Plateau and dissected plateaus. Their landscapes include isolated mountain blocks or successions of mountains of differing elevations, rugged or more or less dissected surfaces as a result of tectonic faulting and folding activity, volcanic activity, the effects of climatic weathering, drainage and plants and animals. There are recently developed steep-sided trenches or channels (classified as gully and rills) of varying widths and depths) in poorly consolidated bedrocks, and weathered sediments or soil on sloping lands in response to intense run-off events. The mountain surfaces are made up of stony and rocky formations without soil development. Dominant rocks are Fossiliferrous limestone,

sandstone, biotite and amphibole, schists, sand and gravel of colluvial and small alluvial deposits in narrow river beds.

They are very shallow soils over continuous rock, and soils that are extremely gravelly or stony. These characteristics make these soils of limited suitability for agriculture.

Vegetation cover is variable, consisting of general open shrubs, general open trees with shrubs and general open herbaceous with shrubs.

Due to the limited amount of soil material in Leptosols, soil profiles were difficult to dig and no soil samples were taken.

Management and use
Leptosols have the most resource potential as areas for wet season grazing and as woodland. Erosion is the greatest threat to large areas of these soils in the study area, due to increasing overexploitation for grazing and wood collection by transhumance and semi-sedentary pastoralism, which appear to determine very high levels of surface stoniness.

Solonchaks (Profiles: no profiles available, bibliographic information)
Solonchaks are soils with a high concentration of soluble salts at certain times of the year. They are located in the playas in the southern part of the study area on the border with Ethiopia. Land cover in the area is mainly bare soil with scattered vegetation, allowing very marginal levels of grazing activity.

Regosols (Profiles: 20, 26, 36, 40, 41, 43, 44, 45, 47, 105, 137, 203)
Regosols comprise all the soils that can not be referred to any of other Reference Soil Groups. These soils are characteristic of arid and semi-arid environments, and due to their aridity the soil profiles do not show diagnostic horizons that may be referred to any of the previous RSG. These soils occur in variable relief types in the landscape, particularly on planation surfaces, slopes, denudational surfaces, mesas and pediments of dissected plateaus; the topography is generally undulating to hilly. The parent material consists of unconsolidated fine-grained material originating from different rock types, including basement complexes, limestone and sandstone.

Vegetation cover of the Regosols in the study area varies from place to place, generally being open shrubs, sparse trees with shrubs, sparse shrubs or general open herbaceous.

Physical and chemical properties
A limited number of soil profile samples were examined for physical and chemical analysis as most of these soils in the study are shallow. The data of the tested soil profiles indicate a uniform sandy loam texture and moderately high bulk density, a strongly to moderately alkaline reaction, are non saline, have high CEC, high base saturation, are strongly calcareous and deficient in nitrogen and phosphorus.

Management and use
Due to the low rainfall and fragile land surface and low moisture-holding capacity of this soil, the Regosols in the study area have minimal agriculture significance, as do the Leptosols. They are used as communal grazing lands and for wood collection.

Prefix qualifiers

According to WRB 2006, the Prefix qualifiers are typically associated qualifiers and intergrade qualifiers; the sequence of the intergrade qualifiers follows that of the RSGs in the WRB Key, with the exception of Arenosols; this intergrade is ranked with the textural suffix qualifiers. The qualifiers should be used before the reference group and give the specific soil diagnostic property that characterises the soil class.

Table 12: Prefix qualifiers

PREFIX	Interpretation
Calcic	Having a calcic horizon or concretions of secondary carbonates between 50 and 100 cm from the soil surface.
Endosalic	Having a salic (salt) horizon starting within 100 cm of the soil surface.
Fluvic	Having fluvic material (fluviatile, marine and lacustrine sediments) in a layer, 25 cm or more thick, within 100 cm of the soil surface.
Grumic	Having a surface layer with a 3 cm or more with a strong structure finer than very coarse granular.
Haplic	Having a typical expression of certain features (typical in the sense that there is no further or meaningful characterisation) and only used if none of the preceding qualifiers applies.
Hypercalcic	Having a strong calcic horizon or concentrations of secondary carbonates starting within 100 cm of the soil surface.
Hyperskeletic	More than 40% (by volume) gravel or other coarse fragments averaged over a depth of 100 cm from the soil surface or to continuous rock or a cemented or indurated layer, whichever is shallower.
Lithic	Having continuous rock starting within 10 cm of the soil surface (in Leptosols only).
Luvic	Having an argic horizon that has a CEC of 24cmol$_c$/kg clay or more throughout or to a depth of 50 cm below its upper limit, whichever is shallower, either starting within 100 cm of the soil surface, or within 200 cm of the soil surface if the argic horizon is overlain by loamy sand or coarse textures throughout, and a base saturation (by1 M NH4OAc) of 50 percent or more in the major part between 50 and 100 cm from the soil surface
Mazic	Having a massive structure and hard to very hard consistency in the upper 20 cm of the soil
Petric	Having a strongly cemented or indurated layer starting within 100 cm of the soil surface.
Vertic	Having a vertic horizon (clayey subsurface horizon that, as a result of shrinking and swelling, has slickensides and wedge-shaped structural aggregates) or vertic properties starting within 100 cm of the soil surface.

4.2.2 General accuracy of the map

After running verification and validation processes, the following results were obtained:

Verification of the map

Forty random points were used for assessing the map quality. The table below shows the 40 random points with the soil classes inferred by the model, and the expected soil classes according to a soil scientist's expert knowledge.

Table 13: Error matrix using Expert Knowledge

The above error matrix gives an overall accuracy level of 87.5% according to expert knowledge. This is due to the general scale of 1:100.000 which controls the predictive process.

Validation of the map

Eighty two soil profiles collected in the field were used to validate the inferred soil map. These profiles were compared with the predicted or inferred soil classes in the same area. Table 12 shows the error matrix obtained through this process.

The error matrix (Table 14) gives an overall accuracy level of 80.4% which is the accuracy at which the map was produced. This demonstrates that the map represents the soil variability of the area under 80.4%.

4.3 Soil map at 1:50 000 scale

A 1:50 000 soil map was produced only for the Agricultural areas of the study area due to the higher number of soil profiles available (from a high sampling density), which were basically the Dur-Dur and Gebiley valleys. The level of classification used in this map was the suffix which gives clearly specific soil attributes or properties to the main soil reference group and prefix level. This study area mainly comprises Vertisols, Calcisols, Fluvisols and Leptosols.

Table 15: Extent of the soil classes

Soil Type	Area (ha)	Area (km^2)	%
Calcaric Grumic Vertisol (Chromic)	31020.46	310.20	46.3

Technosols	4456.08	44.56	0.73
TOTAL	**621468.93**	**6214.69**	**100**

The soils dominating agricultural areas in the Dur-Dur and Gebiley area are the Vertisols (46.3%) the majority of which are used for agriculture. Calcisols, Leptosols and Regosols are found in similar proportions, with calcisols used for agriculture and leptoslols and regisols for grazing and other marginal land uses. Fluvisols are distributed along the rivers and alluvial plains and are used mainly for irrigated orchards. Few Cambisols and Solonchaks are present in the study area.

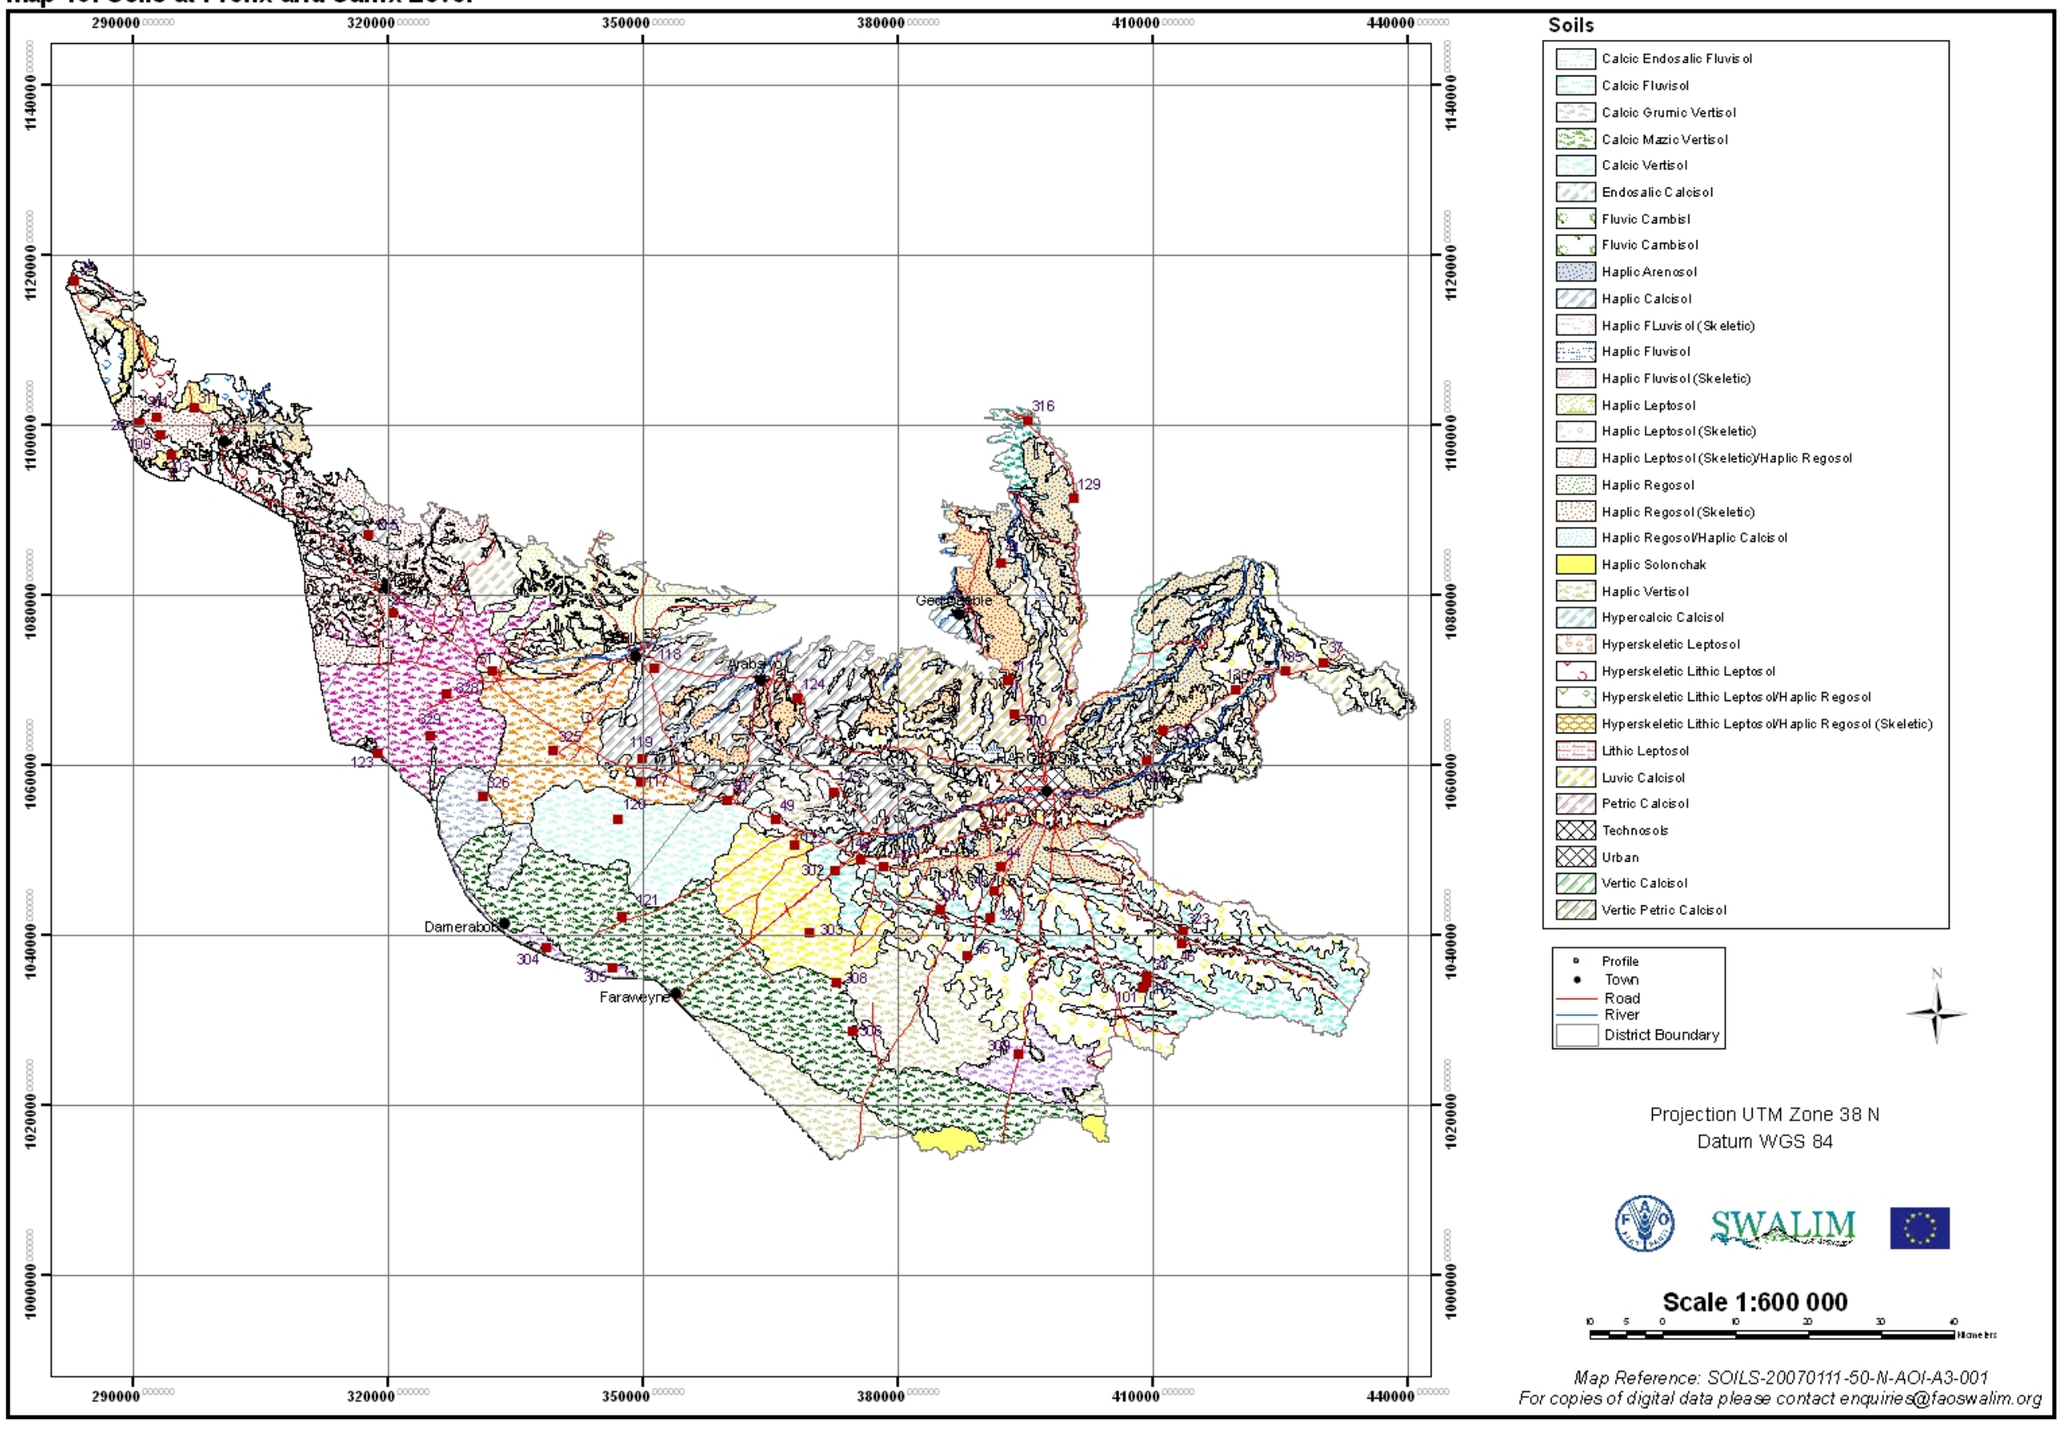
4.3.1 Technical description of the Suffix qualifiers used in the classification

The soils were first characterised at Reference Group level and also at Prefix qualifier level. The Suffix qualifiers were now included which, according to the WRB 2006, are qualifiers aimed at describing diagnostic horizons, properties or materials. They can also be qualifiers relating to chemical and/or physical characteristics. Descriptions of Suffix qualifiers used are found in Table 16.

Table 16: Suffix qualifiers and its technical meaning

SUFFIX	TECHNICAL MEANING
Aridic	Having *aridic* properties without takyric or yermic horizon. Aridic properties combine a number of properties that are common in surface horizons of soils occurring under arid conditions and where pedogenesis exceeds new accumulation at the soil surface by Aeolian or alluvial activity.
Arenic	Having a texture of loamy fine sand or coarser in a layer, 30 cm or more thick, within 100 cm of the soil surface.
Bathyhyposalic	Salic (salt) horizon starting between 100 - 200 cm from the surface.
Bathyhyposodic	Sodic horizon having more than 6% saturation with exchangeable sodium between 100 - 200 cm from the surface.
Calcaric	Having *calcaric* material between 20 - 50 cm from the soil surface or between 20 cm and a continuous rock or a cemented or indurated layer, whichever is shallower. Calcaric material applies to material that contains 2% or more calcium carbonate equivalent.
Chromic	Having within 150 cm of the soil surface a subsurface layer, 30 cm or more thick, that has a Munsell hue redder than 7.5YR or that has both, a hue of 7.5 YR and a chroma, moist, of more than 4.
Clayic	Having a texture of clay in a layer, 30 cm or more thick, within 1,000 cm of the soil surface
Dystric	Having a base saturation (by 1 M NH_4OAc) of less than 50% in the major part between 20 - 100 cm from the soil surface or between 20 cm and continuous rock or a cemented or indurated layer, or, in Leptosols, in a layer, 5 cm or more thick, directly above continuous rock
Epihyposodic	Having 15% or more exchangeable Na plus Mg on the exchange complex within 50 cm of the soil surface.
Episkeletic	Having 40% or more (by volume) gravel or other coarse fragments averaged within 50 cm of the soil surface.
Hyposalic	Having an ECe of 4 dSm^{-1} or more at 25° C in some layer within 100 cm of the soil surface.
Hyposodic	Having 6% or more exchangeable on the exchange complex in a layer, 20 cm or more thick, within 100 cm of the soil surface.
Siltic	Having a texture of silt, silt loam, silty clay loam or silty clay in a layer, 30 cm or more thick, within 100 cm of the soil surface.
Skeletic	40% or more (by volume) gravel or other coarse fragments averaged over a depth of 100 cm from the soil surface or to continuous rock or a cemented or indurated layer, whichever is shallower.

Map 10: Soils at Prefix and Suffix Level



4.4 Technical assessment of the soil resource in the study area

Table 17 gives a general idea of the main properties of the different soil classes at Reference group level. The potentialities and limitations of each soil class were expressed on a theoretical basis (soil reference books and the author's experience) and expert knowledge.

Table 17: Technical assessment of the soil resource

SOIL CLASS	PHYSICAL PROPERTIES	CHEMICAL PROPERTIES	RECOMMENDED LAND USE	LIMITATIONS
Vertisols	➢ Located on flat to slightly sloping surfaces. ➢ Low bulk density ➢ Dark colours ➢ Clayey texture ➢ Grumic/granular surface structure. ➢ Deep soils ➢ Angular/subangular blocky, prismatic subsurface horizons. ➢ Deep and wide vertical cracking structure. ➢ Wedge-shaped structure and slickenside development in lower layers. ➢ Churning or pedoturbation. ➢ Slow water conductivity ➢ Relatively high water holding capacity. ➢ Very hard below the surface horizon when dry; plastic and sticky when wet.	➢ Low organic matter content ➢ Low content of nitrogen and phosphorus nutrients. ➢ pH: slightly to moderately alkaline. ➢ EC: Negligible or slightly saline. ➢ Low Exchangeable sodium. ➢ CEC: Moderate ➢ High base saturation. ➢ High accumulation of lime. ➢ Dominant cations calcium and magnesium.	➢ Considered fertile soil where most agricultural land is found. ➢ Good potential production under specific soil management practices.	➢ Very susceptible to erosion: sheet, rill, and gully erosion, especially under poor water harvesting practices. ➢ Soil crusting at the surface is frequent. ➢ Soil severely waterlogged during high rainfall periods. ➢ Difficult to plough with oxen-drawn implements. ➢ Difficult to cultivate with heavy machinery. ➢ Poor trafficability when wet. ➢ Sub-surface piping through cracks and sinkholes.
Calcisols	➢ Well drained ➢ Good water holding capacity.	➢ Good amount of soil nutrients. ➢ Highly calcareous	➢ Good alternative for agriculture use due to their physical properties.	➢ Stoniness of the surface or close to the surface in some parts. ➢ Aridity ➢ Salinity in lower horizons. ➢ High pH and/or high calcium content limits the availability of some nutrients.
Fluvisol	➢ Located on flat to gently undulating surface. ➢ Young soils along rivers ➢ Good water conductivity	➢ Irregular organic content with depth. ➢ Salinity in lower layers locally.	➢ Good drainage conditions. ➢ Accumulation of yearly fertile soil material.	➢ Periodical flooding ➢ No major soil development.

	➢ Mainly light soil texture classes.			
Leptosols	➢ Very shallow soils ➢ High soil stoniness ➢ Excessive internal drainage.	➢ Very poor fertility	➢ Not suitable for any specific use. Mainly conservation.	➢ Shallow depth. ➢ Soil stoniness and gravel content.
Cambisols	➢ Loamy textures	➢ Medium fertility	➢ Irrigated farming ➢ Extensive grazing land	➢ Severe eroding land in mountain areas.
Regosols	➢ Weakly developed mineral soil in unconsolidated material. ➢ Shallow or stony soil	➢ Poor fertility	➢ Extensive grazing	➢ Delicate and severely eroding soils. ➢ Poor fertility ➢ Erosion and soil stoniness.
Arenosols	➢ Sandy soils developed in active sand dunes. ➢ Extremely drained	➢ Very poor fertility ➢ Saline soils	➢ Extensive nomadic grazing.	➢ Wind erosion ➢ Salinity ➢ Soil texture (sandy)
Solonchaks	➢ Heavy texture soils ➢ Low water conductivity	➢ Very saline soils	➢ Conservation	➢ Salinity ➢ Texture

The main aspects that should be highlighted with regard to soil resources in the study area are related to:

Soil erosion

Soil erosion is the primary problem in the study area. Water and wind erosion are present all over the territory and have a huge influence on the status of the soil resource and the overall environment. Sheet, rill and gully erosion are present at different levels of severity. Soil erosion problems as observed in the field and according to land users, can be attributed to natural conditions and to land mismanagement, especially increased levels of livestock grazing (overstocking), increases in numbers of water points (hand-wells, boreholes and underground water reservoirs or berkado), increasing devegetation (tree cutting, forage cutting) and some water harvesting techniques applied in agricultural areas. As the severity of soil erosion in agropastoral areas was noticed previously, two soil conservation and water harvesting projects were implemented during the 1980s and in 2000. Specifically, soil bunding was practiced in all the agricultural areas in the Plateau and dissected plateau between Hargeisa, Gebiley and Borama. In some areas it is very common to see old and unmaintained soil contour bunds together with gullies and rills, sometimes partly reduced in height through time either inside or around the fields. These soil bunds were reported as being established in the 1980s by the North-west Agricultural Development Project [24], which included soil water conservation programmes. Several newer bunds were recently made both in support of farmers practicing soil conservation, but mainly for water harvesting purposes.

It is noteworthy that wind erosion problems are severe and no conservation measures are in place.

Much of the erosion problems are recent, but they have advanced significantly during the past 20 years and more intensively after the end of the civil war in 1991. During this period the majority of pastoralists in the region altered their livelihood from nomadic herding to sedentary agropastoralism as a primary source of livelihood. The open grazing lands have been reduced both in extent and access, and traditional grazing has mostly been substituted by private farming, with permanent enclosures created without legal

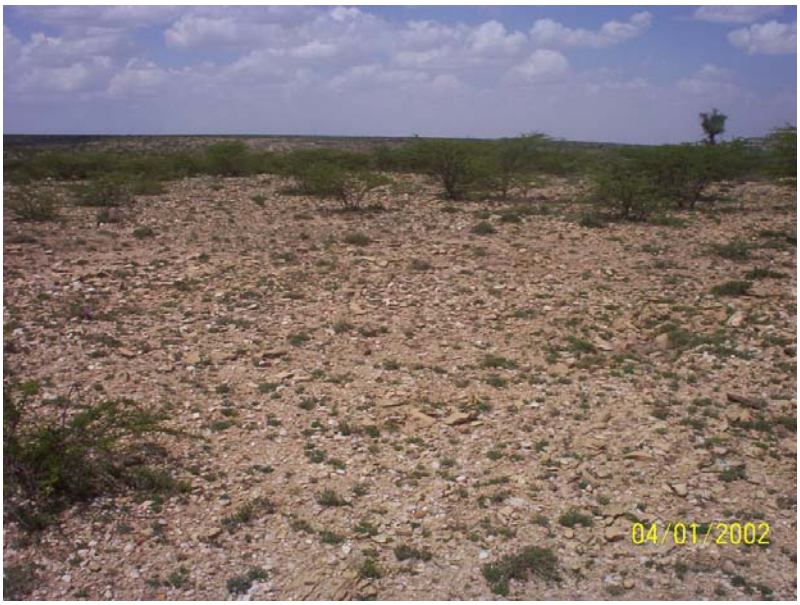
restrictions or grazing controls. Privately acquired lands are used for grazing family stock or used for grass harvesting or wood collection. The ever-increasing pressure on land resources is aggravated by an increased number of water points (wells and berkeds), and a lack of knowledge and skills amongst new farmers.

Deep soils as a natural resource are limited in the study area due to its arid and semi-arid climate. Soil formation is a very slow process, and the small existing amounts of soil are being washed away, making the situation even worse for land users.

Picture 1: Consequences of lack of maintaince of a soil bunding

Soil stoniness

A result of soil erosion is an increase in stoniness on the soil surface. Approximately, 45% of the soils in the study area are graded between “Many” (15 - 40% of coverage) and “Abundant” (40 - 80% of coverage) classes of soil stoniness. Soil stoniness is one of the main indicators for assessing land degradation as it is a sign of several degradational processes, usually in an advanced stage, occurring on the land. Its presence constrains cropping, grazing, forest development and even wildlife.



Picture 2: Soil stoniness

Soil fertility

Soil fertility is one of the main soil resources available in the study area especially for agropastoralism. According to laboratory results (Table 18) the soils of the study area are below the standard deficiency level (see Annex 2) which clearly shows the poor fertility status of the different soil classes.

Table 18: Fertility levels

SOIL CLASS	FERTILITY LEVELS					SALINITY	CALCIUM CARBONATE
	Organic matter	Nitrogen	Phosphorus	Potassium	pH		
Vertisols	Deficient	Deficient	Deficient	Low	Moderately to strongly	Non saline to slightly saline	Strongly calcareous
Fluvisols	Deficient	Deficient	Deficient to rarely adequate	Low	Moderately to strongly	Non saline	Strongly calcareous
Calcisols	Deficient	Deficient	Deficient to adequate	Low	Moderately alkaline	Non saline	Strongly calcareous
Cambisols	Deficient	Deficient	Adequate	Low	Moderately alkaline	Non saline	Strongly calcareous
Regosols	Deficient	Deficient	Deficient	Low	Moderately alkaline	Non saline	Calcareous to strongly calcareous
Arenosols	Deficient	Deficient	Deficient	Moderate to high	Strongly alkaline	Non saline	Calcareous to strongly calcareous
*Leptosols**	*not analyzed due to their natural limitations for sampling.						
Solonchack	Deficient	Deficient	Deficient	Low	Strongly alkaline	Saline to strongly saline	Strongly calcareous

Fertility problems occur in all soil classes in the study area but particularly in those used for agriculture, due to the unfavourable arid and semi-arid environment and also the fact that farmers do not replace minerals taken from the soil after harvest. Very few or no mineral or organic fertilizers are used, and available manure is kept outside fields because farmers feel that incorporating fresh manure into fields causes the appearance of weeds, making farming more difficult. They also fear the ticks that are present in the manure (Picture 3).

All soil classes in the study area are calcareous due to the underlying parent material. This fact doesn't have significant implications for the soil behaviour as such, but these soils are vulnerable to soil erosion because of their physical and chemical properties.

Salinity is not a problem in the area, with the exception of two small areas in the southern part where saline soils are found.

Picture 3: Available manure that is not used in the fields

5 CONCLUSIONS AND RECOMMENDATIONS

This study produced soil data using a multiscale and multi-user approach so that users dealing with natural resources management and other applications might make ready use of the different types of soil data presented here.

Most soils in the study area belong to a class denoting very limited soil development. 45% of the study area is composed by rocky/stony soils which have limitated use for agriculture. The origins of these type of soils are due to their natural geographic context expressed by a hilly terrain and arid climate, and to some human activities which further diminish the existing limited soil resources.

Soil stoniness is a common feature in the study area, particularly where soil erosion is high both in extent and severity. It is advisable that this process be studied in detail under a comprehensive Land Degradation Assessment of the study area. This will determine the main causes and will also find integrated solutions as part of a Natural Resources Management (NRM) strategy.

Soil fertility in the study area is low. Soils are being degraded continuously in the agro-pastoral areas, where almost no organic or inorganic fertilizers are applied. Present and future extension service activities should include the creation of awareness amongst farmers of serious declining soil fertility, and development of strategies to improve practices in the present farming systems. Research into the management and application of manure appropriate for the area is required.

A soil management strategy should be proposed in relation to a NRM strategy that can later be adopted by land users in the study area, otherwise soil degradation will continue to increase both in extent and severity, resulting in very low productivity and direct negative effects in terms of socio-economic and environmental status.

Rock outcrops : Few	
Surface stoniness : Dominant	**UTM coordinates**: 290726 - 1100306

Remarks :	Profiles are impossible because this soil is dominated by stones. Usually located in valleys surrounded by hills. Soil erodes away due to overgrazing. Rock outcrops are present. The area is used for grazing and many succulent plants are present. Mineral soil with lithic contact developed in sandstone with highly $CaCO^3$ and metamorphic rocks. This soil type is spread through the whole area.

SOIL PROFILE DESCRIPTION

Profile code : 21	**Date :** 2006-05-31

Location : Lebida	**Coordinates :** 10º05'14" / 43º46'23"

Authors : Omar Haji Duale	**Soil climate :** Aridic
WRB 2006 Soil classification: Lithic Leptosol	**Land form :** Hill
FAO 90 classification :	**Land element :** Slope
Effective soil depth: 0 -25cm	**Drainage :** Well
Rock outcrops : Common	**Moisture conditions :** Dry
Surface stoniness : Dominant	**UTM coordinates:** 365559 - 1115328

Remarks :	This soil is found under a basement complex material in hilland. There are no salts and the presence of rock outcrops is usual. There is a very little soil development between the rocks. The site corresponds to the shoulder of the slope.

SOIL PROFILE DESCRIPTION

Profile code : 102	**Date :** 2006-05-20

Location : Toon-maadhyaal	**Coordinates :** 09º21'21" / 44º10'27"
Authors : Omar Haji Duale, Musse Shaie, Ali Ibrahim Ismail	**Land form :** Valley
WRB2006 Soil Classification: Calcic Vertisol (Chromic)	**Land element :** Slope
Land use : Shifting cultivation	**Drainage :** Well
Effective soil depth: 100-150cm	**Moisture conditions :** Dry
Surface stoniness : Nil	**Vegetation :** Grassland
UTM coordinates: 409341 - 1034321	
Remarks : Very hard soil located at the talus slope of a valley, very close to profile 201. Soil is clayed but is very compacted and dry, so, many properties were difficult to see. Although the soil texture is clay, there is no evidence of cracks. Gilgai microtopography was found.	

Horizon	Depth cm	Description
A1	0-20	Dark brown (7.5YR 4/4) (dry); no mottles; clay; weak very fine granular structure; no cutans; many Voids fine; no rocks; extremely calcareous; common fine-medium roots; gradual smooth boundary.
A2	20-30	Reddish brown (5YR 4/4) (dry); no mottles; clay; moderate medium granular structure; no cutans; few Voids fine; no rocks; extremely calcareous; common fine roots; gradual smooth boundary.
B1	30-50	Dark reddish brown (5YR 3/3) (dry); no mottles; clay; moderate medium subangular blocky structure; many pressure faces; very few, very fine Voids; no rocks; extremely calcareous; common very fine roots; gradual smooth boundary.
B2	50-65	Brown (7.5YR 4/3) (dry); no mottles; clay; moderate medium angular blocky structure; many pressure faces; no voids; no rocks; extremely calcareous; common very fine roots; gradual smooth boundary.
C	65-130	Brown (7.5YR 4/3) (dry); no mottles; clay; massive structure; no cutans; no voids; no rocks; extremely calcareous; very few very fine roots.

SOIL PROFILE DESCRIPTION

Profile code : 105	**Date :** 2006-05-29

Location : Lurega Meygaaga	**Coordinates :** 10º23'01" / 43º49'42"
Authors : Musse Shaie	**Land form :** Pediment
WRB 2006Soil Classification: Haplic Regosol (Calcaric, Aridic)	**Drainage :** Moderately well
Effective soil depth: 100-150cm	**Moisture conditions :** Dry
Rock outcrops : Nil	
Surface stoniness : Few	**UTM coordinates:** 371735 - 1148073

Remarks : Piedmont, alluvial plain. Grazing land use. Soils are very little developed under Limestone. There are no salts and there are soil cracks (fine width and very widely spaced). The landform is a braided valley.

Horizon	Depth cm	Description
A1	0-10	Brown (7.5YR 5/2) (moist) and Pale brown (10YR 6/3) (dry); no mottles; sandy loam; massive structure; no cutans; ; few Voids medium; no rocks; slightly calcareous; common fine roots; clear smooth boundary.
A2	10-65	Brown (7.5YR 4/3) (moist) and Brown (7.5YR 5/3) (dry); no mottles ; sandy loam; massive structure; no cutans; few Voids coarse; common fine and medium subrounded rocks; moderately calcareous; few medium-coarse roots; clear smooth boundary.
Ck	65-150	Brown to dark brown (7.5YR 4/2) (moist) and Brown (7.5YR 5/3) (dry); no mottles; sandy loam; massive structure; no cutans; very few Voids very coarse; no rocks; strongly calcareous; no roots.

SOIL PROFILE DESCRIPTION

Profile code : 119	**Date :** 2006-06-18

Location : Ijjara	**Coordinates :** 09º35'35" / 43º38'04"
Authors : Omar Haji Duale, Musse Shaie	**Soil climate :** Aridic
WRB 2006 Soil Classification: Vertic Calcisol (Aridic, Clayic).	**Land form :** Plateau
Land use : Agriculture	**Drainage :** Moderately well
Effective soil depth: 100-150cm	**Moisture conditions :** Dry
Rock outcrops : Nil	
Surface stoniness : Very few	**UTM coordinates:** 350035 - 1060743

Remarks : Soil developed in a plateau/denudational surface under limestone. Fallow agricultural land. Fine very closely spaced cracks. No salts are present.

Horizon	Depth cm	Description
A1	0-20	Dark brown (7.5YR 3/2) (moist) and Brown (7.5YR 5/3) (dry); no mottles; weak very fine granular structure; no cutans; very few, very fine Voids; no rocks; strongly calcareous; many fine-medium roots; clear wavy boundary.
A2	20-42	Dark brown (7.5YR 3/2) (moist) and Brown (7.5YR 5/3) (dry); no mottles ; moderate medium subangular blocky structure; no cutans; ; very few, very fine Voids; no rocks; few fine calcareous nodules; strongly calcareous; few earthworms; few medium roots; clear wavy boundary.
C1	42-65	Brown (7.5YR 4/3) (moist) and Brown (7.5YR 5/3) (dry); no mottles; moderate medium subangular blocky structure; no cutans; ; very few, very fine Voids; no rocks; many calcareous concretions medium; extremely calcareous; no roots; clear irregular boundary.
C2k	65-150	Strong brown (7.5YR 4/6) (moist) and Strong brown (7.5YR 5/6) (dry); massive structure; no cutans; very few, very fine Voids; no rocks; abundant calcareous concretions medium; extremely calcareous; no roots.

SOIL PROFILE DESCRIPTION

Profile code : 304	**Date :** 2006-07-02

Location : Allaybaday	**Coordinates :** 09º23'31" / 43º31'52"
Authors : Omar Haji Duale, Ali Ibrahim Ismail	**Soil climate :** Aridic
WRB 2006 Soil Classification: Calcic Mazic Vertisol (Bathyhyposodic, Bathyhyposalic).	**Land form :** Alluvial plain
Effective soil depth: 100-150cm	**Drainage :** Well
Rock outcrops : Nil	**Moisture conditions :** Dry
Surface stoniness : Nil	**UTM coordinates:** 338710 - 1038520

Remarks : Parent material is silt, clay and loam located in a Piedmont/Alluvial plain. No salt crusts are present, instead soil cracks of fine width and very closely spaced are present.

Horizon	Depth cm	Description
A1	0-15	Dark brown (7.5YR 3/2) (moist) and Brown (7.5YR 4/3) (dry); no mottles; weak fine granular structure; no cutans; very few, very fine Voids; no rocks; extremely calcareous; many very fine roots; clear wavy boundary.
A2	15-40	Dark brown (7.5YR 3/2) (moist) and Dark brown (7.5YR 3/3) (dry); no mottles; moderate medium subangular blocky structure; no cutans; very few, very fine Voids; no rocks; extremely calcareous; few very fine roots; clear smooth boundary.
Bt	40-100	Dark brown (7.5YR 3/2) (moist) and Dark brown (7.5YR 3/3) (dry); no mottles; strong coarse angular blocky structure; common pressure face Cutans; very few, very fine Voids; no rocks; extremely calcareous; very few very fine roots; diffuse smooth boundary.
C	100-130	Dark brown (7.5YR 3/3) (moist) and Dark brown (7.5YR 3/4) (dry); no mottles; moderate medium angular blocky structure; no cutans; very few, very fine Voids; no rocks; extremely calcareous; no roots.

SOIL PROFILE DESCRIPTION

Profile code : 317	**Date :** 2006-07-14

Location : North of Luina Dhexe	**Coordinates :** 10º00'50" / 44º08'18"
Authors : Omar Haji Duale, Ali Ibrahim Ismail	**Soil climate :** Aridic
WRB 2006 Soil Classification: Vertic Petric Calcisol (Aridic, Clayic).	**Land form :** Plateau
Effective soil depth: 50-100cm	**Drainage :** Well
Rock outcrops : Nil	**Moisture conditions :** Dry
Surface stoniness : Few	**UTM coordinates:** 405573 - 1107070

Remarks : Soil profile located in a Dissected plateau/Pediment with parent material calcaric rock and limestone. Fine width very closely spaced cracks are present whereas salt crusts are absent. The C horizon constitutes a $CaCO^3$ parent rock present as a form of rocks and concretions. This horizon was not sampled.

Horizon	Depth cm	Description
A	0-10	Dark brown (7.5YR 3/2) (moist) and dark brown (7.5YR 4/4) (dry); no mottles ; weak fine granular structure; no cutans; ; no voids; few fine subrounded rocks; extremely calcareous; common fine-medium roots; clear smooth boundary.
AB	10-20	Very dark Grey (7.5YR 3/1) (moist) and Dark brown (7.5YR 3/2) (dry); no mottles; strong medium subangular blocky structure; no cutans; no voids; very few fine subrounded rocks; extremely calcareous; common fine-medium roots; gradual wavy boundary.
B	20-65	Very dark Grey (7.5YR 3/1) (moist) and Very dark Grey (7.5YR 3/1) (dry); no mottles; strong medium angular blocky structure; common pressure face Cutans; no voids; very few fine subrounded rocks; extremely calcareous; few fine roots; clear wavy boundary.
C	65-110	No mottles; dominant limestone stones and boulders subrounded fresh-slightly weathered rocks; extremely calcareous.
